#### Abstract

Graph rewrite formalisms are a powerful approach to modeling complex molecular systems. They capture the intrinsic concurrency of molecular interactions, thereby enabling a formal notion of mechanism (a partially ordered set of events) that explains how a system achieves a particular outcome given a set of rewrite rules. It is then useful to verify whether the mechanisms that emerge from a given model comply with empirical observations about their mutual interference. In this work, our objective is to determine whether a specific event in the mechanism for achieving X prevents or promotes the occurrence of a specific event in the mechanism for achieving Y. Such checks might also be used to hypothesize rules that would bring model mechanisms in compliance with observations. We define a rigorous framework for defining the concept of interference (positive or negative) between mechanisms induced by a system of graph-rewrite rules and for establishing whether an asserted influence can be realized given two mechanisms as an input.

## 1 Introduction

A persistent challenge across molecular biology is to understand how a multitude of diverse and asynchronous interactions between molecular entities give rise to coherent system behavior. One difficulty arises from the combinatorial complexity inherent in chemistry: A reaction (or interaction) between structured entities, such as molecules, consists in the transformation of specific parts in a manner that depends on a few rather than all aspects specifying the reactants. Combinatorial complexity then arises because a given reactant combination can exhibit several distinct reactive patterns and the same pattern can occur across many distinct reactant combinations. This idea generalizes beyond chemistry.

A molecular system can thus be described in terms of rewrite rules. In this way, rule-based modeling tackles combinatorial complexity without succumbing to it because it only specifies rules of pattern transformation and not the multitude of possible carriers of these patterns. Many physical systems can be conveniently described as graphs. A rule-based approach then becomes a graph rewriting formalism with a domain-specific execution model that determines the probability with which a rule fires at a given time. The currently most developed approaches are the Kappa language [?, ?] and BNGL [?] for molecular biology and Mød [?] for organic chemistry.

A rule formalizes the interaction between physical entities at some chosen level of abstraction. Processes occurring below that level are abstracted away, yet not ignored: They inform what a rule should say, but they are not explicitly represented by it. For instance, in organic chemistry, a rule of reaction between molecules expresses a local reconfiguration of bonds among atoms without explicitly representing the underlying mechanism of electron pushing that engenders such reconfiguration. In molecular biology, an interaction between proteins is typically expressed by asserting the conditions for a change of protein state without representing the structural mechanisms enabling that change. In essence, a mechanism below the chosen abstraction level becomes an axiomatic rule at the abstraction level [?].

Many observations of system behavior are assertions rather than rules. For example, an assertion might claim that the activation of protein $X$ inhibits the assembly of molecular machine $Z$. It is desirable to determine whether and why an assertion holds in terms of the joint action among rules that represent a particular system. This is tantamount to providing a mechanism that explains a given assertion at the level of abstraction at which rules are defined.

The stochastic application of rules (a simulation) typically generates a long trace of state transitions. A mechanism is a set of transitions that were jointly necessary in producing a specified outcome. Mechanisms so-defined can be extracted from traces [?, ?] and abstracted into partial orders (posets) of events 1

Here we propose a formal logic to express and verify a particular kind of assertion about a model written in the Kappa language. We focus on assertions in which the occurrence of one event is claimed to interfere with another event. Our approach takes as input two posets of events (i.e. mechanisms), which might be hypothesized or abstracted from a simulation, and provides evidence whether the two posets interfere with one another at the specified events. The key is that each poset builds up a context that is required for its terminal event. These contexts can be reconstructed and checked for mutual consistency. To lay the foundation for this approach requires setting up some formal machinery which occupies the bulk of this paper.
Interaction between graph rewriting posets. The graphs in Kappa consist of nodes, called agents, meant to represent proteins. Agents are equipped with sites through which they connect to one another. A site represents a resource and hence can bear at most one edge. Such graphs are called sitegraphs.

An event is the application of a rewrite rule to

Figure 1: A Kappa model. a usually large graph representing the state of the system. Events are partially ordered by a relation of precedence. Intuitively, an event $e_{1}$ precedes an event $e_{2}$ if $e_{1}$ contributes to establishing the context necessary for $e_{2}$. Consider, for example, the simple model in Figure 1 with the initial state consisting of nodes $\{A, B, C\}$, all unbound. Suppose furthermore that the binding of agent X to A (rule $r_{\mathrm{AX}}$ ) and of agent Y to A (rule $r_{\mathrm{AY}}$ ) are two significant events $e_{\mathrm{AX}}$ and $e_{\mathrm{AY}}$, respectively. We wish to verify the assertion that either event inhibits the other. The assertion is cast in terms of two mechanisms (posets) that could have been extracted from a simulation trace of this model, one mechanism resulting in $e_{\mathrm{AX}}$, the other in $e_{\mathrm{AY}}$ (Figure 2A).
A static inspection of rules $r_{\mathrm{AX}}$ and $r_{\mathrm{AY}}$, underlying the events that are the subject of our query, shows that both use the same site of A. This might suggest that the two events are in conflict and therefore inhibit each other. This, however, is not a valid conclusion. Given the poset AX of Figure 2A, we can reconstruct the context-specifically the site-graph $G_{\mathrm{AX}}$ of Figure 2 B —in which rule $r_{\mathrm{AX}}$ fires. Note that $G_{\mathrm{AX}}$ specifies that site 2 of A must be unbound. Likewise, the firing of rule $r_{\mathrm{AY}}$ is contingent upon context $G_{\mathrm{AY}}$, which is built up by poset AY. $G_{\mathrm{AY}}$ requires that site 2 of A be bound. These two contexts are in conflict and thus cannot be realized at the same time. This means, in turn, that there is no inhibition at this point between the two mechanisms: Whether a particular A gets bound to X or to Y is already decided before the mechanisms reach the events whose relationship of inhibition we queried. As a whole, the mechanisms AX and AY must interfere with one another negatively, as A cannot be bound to both X and

[^0]

Figure 2: Panel A: Two mechanisms (posets) and a query for conflict between the specified events. Black arrows are precedence; events are labeled by the underlying rules. Panel B: The graph $G_{\mathrm{AX}}$ represent the context in which the rule $r_{\mathrm{AX}}$ is applied in the Poset AX. There is no scenario in which the posets interact, since the graph $G$ is not a site-graph. The site 3 of agent A has to be bound to an agent C and be free at the same time, which is not representable in site-graphs.

Y at the same time; but the point of conflict is somewhere else. (It is between event $r_{\mathrm{AB}}$ and $r_{\mathrm{AY}}$.) To determine the earliest event combination at which two mechanisms conflict with one another can be done by scanning all events of one against all events of the other.

If we change the model by replacing rule $r_{\mathrm{AB}}$ with rule $r_{\mathrm{AB}}^{\prime}$ (Figure 3), the context for the application of rule $r_{\mathrm{AX}}$ becomes consistent with the context of application of rule $r_{\mathrm{AY}}$. This means both rules can fire. Since the firing of $r_{\mathrm{AX}}$ destroys part of the context needed by $r_{\text {AY }}$ (and vice versa), the mechanisms inhibit each other at the events queried. In sum, the key in determining whether two events in the scope of distinct mechanisms are mutually exclusive consists in reconstructing from the given mechanisms the context required for both events and determining whether it can be realized. We call this critical context a "scenario".

Related work. The notion of rule influence, introduced in Refs. [?, ?], is used to detect inhibition and promotion between posets (Definition 18). Our approach to abstracting traces of state transitions into partial orders is similar to Refs. [?, ?], but we use more fine-grained relations on graphs (the enablement and prevention relations of Section 2.4. As a consequence, we do not need Petri nets as an intermediate encoding between state transitions and posets. In any case, our main focus is on reconstructing a trace from a poset, which is obtained from a causal structure extracted from a Kappa simulation. This extraction is the subject of Ref. [?] and outside the scope of this paper.

Outline. In Section 2 we introduce site-graphs, the graph rewriting framework of Kappa, and the notion of rule influence. To define partial orders between events in a manner informed by rule influence, we need to take a detour via the transition system induced by the rules (Section 2.4). In order to determine the scenario that establishes enablement or prevention between posets, we need to reconstruct a trace from a poset. To this end, in Section 3, we formalize trace reconstruction as the reverse of poset abstraction from traces. In Section 4 we define a logic for expressing assertions on the posets provided as inputs. We conclude in Section 5.

Length limitations preclude a description of our implementation, which can be found at https:// github.com/Kappa-Dev/PosetLogic. All constructions on site-graphs presented here can be adapted to simple graphs.

## 2 Graph rewriting and transition systems

### 2.1 Site-graphs

Let A be a set of agents, ranged over by $\mathrm{a}, \mathrm{b}$ and $\mathrm{K}=\{A, B, .$.$\} be a set of agent types, equipped with a$ map site : $\mathrm{K} \rightarrow \mathbb{N}_{>0}$. The function type: $\mathrm{A} \rightarrow \mathrm{K}$ assigns a type to each agent.
Definition 1 (Site-graph). A site-graph is a structure $(\mathscr{A}, \mathscr{N}, \mathscr{E})$ where

- $\mathscr{A} \subseteq \mathrm{A}$ is a set of agents;
- $\mathscr{N} \subseteq \mathscr{A} \times \mathbb{N}_{>0} \uplus\{$ free $\}$ is a set of nodes, with a special node free, and where each non-free node is a pair ( $\mathrm{a}, i$ ) of an agent $\mathrm{a} \in \mathscr{A}$ and site $i<\operatorname{site}($ type $(\mathrm{a}))$;
- $\mathscr{E} \subseteq \mathscr{N} \times \mathscr{N}$ is a symmetric set of edges with the constraint that it is conflict-free: $\forall\left(n_{1}, n_{2}\right),\left(n_{1}^{\prime}, n_{2}^{\prime}\right) \in$ $\mathscr{E},\left(n_{1}=n_{1}^{\prime} \wedge n_{2}=n_{2}^{\prime}\right) \vee\left(n_{1}=n_{2}^{\prime} \wedge n_{2}=n_{1}^{\prime}\right) \vee\left(\left\{n_{1}, n_{2}\right\} \cap\left\{n_{1}^{\prime}, n_{2}^{\prime}\right\} \subseteq\{\right.$ free $\left.\}\right)$.
Definition 2 (Morphism on site-graphs). A morphism $f: G \rightarrow H$, for $G$ and $H$ two site-graphs, is a pair of functions $f=(v, e)$ with
- $v: \mathscr{A}_{G} \rightarrow \mathscr{A}_{H}$ a function on agents that preserves types: type $(v(\mathrm{a}))=$ type(a) and that can be extended to a function on nodes: $v(\mathrm{a}, i)=(v(\mathrm{a}), i)$ and $v($ free $)=$ free, for all $\mathrm{a} \in \mathscr{A}_{G}$ and for all $i<$ site(type(a));
- and $e: \mathscr{E}_{G} \rightarrow \mathscr{E}_{H}$ a function on edges such that for any two nodes $n_{1}, n_{2} \in \mathscr{N}_{G}$, if $\left(n_{1}, n_{2}\right) \in \mathscr{E}_{G}$ then $e\left(n_{1}, n_{2}\right)=\left(v\left(n_{1}\right), v\left(n_{2}\right)\right)$.
Site-graphs and their morphisms form a category, denoted $\mathscr{G}$. Morphisms in $\mathscr{G}$ preserve the node type and the edge structure of nodes in site-graphs. Isomorphisms are denoted with $\cong$. A mono is a morphism with injective functions on nodes and edges. We denote the empty graph with $\varepsilon$ and write $\vec{f}=\left\langle f_{1}, f_{2}\right\rangle$ for the span $G_{1} \stackrel{f_{1}}{\leftarrow} G_{2} \xrightarrow{f_{2}} G_{3}$. The same notation is used to denote the cospan $G_{1} \stackrel{f_{1}}{\rightarrow} G_{2} \stackrel{f_{2}}{f_{3}}$. For simplicity, we write $f$ for $v$ (or $e)$ in $f=(v, e)$. Finally, we write $\operatorname{hom}(\mathscr{G})$ and $\operatorname{span}(\mathscr{G})$ for the class of morphisms and spans of $\mathscr{G}$, respectively.

### 2.2 Graph rewriting

A rule-based model consists of graph-rewriting rules that are applied in a stochastic fashion to a typically large graph representing the state of a system. In Kappa the stochastic application of rewrite rules follows basic principles of stochastic chemical kinetics [?, ?]. Each graph-rewrite action constitutes a state transition and a temporal sequence of such transitions is a trace. We also refer to the state of the system as a "mixture".
Definition 3 (Pushout). The pushout of a span $\vec{g}$ is a cospan $\vec{f}$ such that $f_{1} g_{1}=f_{2} g_{2}{ }^{2}$ and such that for any other cospan $\overrightarrow{f^{\prime}}$ for which $f_{1}^{\prime} g_{1}=f_{2}^{\prime} g_{2}$, there is a unique morphism $M \rightarrow M^{\prime}$ that makes diagram PO below commute.

In the category of site-graphs, the pushout does not always exist. For a span $\vec{g}$ of monos, if the pushout exists, then it asserts a gluing of $G_{1}$ and $G_{2}$, resulting in $M$, based on the identifications (gluing instructions) expressed by $\vec{g}$.
Definition 4 (Rule). A rule is a span of monos $\vec{r}=L \stackrel{p}{\leftarrow} K \xrightarrow{q} R$ such that for some $\mathrm{a} \in \mathscr{A}_{K}$ and $i<$ site $(\operatorname{type}(\mathrm{a}))$, if $(\mathrm{a}, i) \in \mathscr{N}_{K}$ then $((q(\mathrm{a}), i), n) \in \mathscr{E}_{R} \Longleftrightarrow\left((p(\mathrm{a}), i), n^{\prime}\right) \in \mathscr{E}_{L}$, with $n \in \mathscr{N}_{R}$ and $n^{\prime} \in \mathscr{N}_{L}$.

[^1]In site-graphs the site of an agent can be specified without specifying if the site is free or bound to another site. Formally, in a site-graph $G$ with an agent a $\in \mathscr{A}_{G}$, we can have $(\mathrm{a}, i) \in \mathscr{N}_{G}$ for which there is no edge $\left(n_{1}, n_{2}\right) \in \mathscr{E}_{G}$ such that $n_{1}=(\mathrm{a}, i)$ or $n_{2}=(\mathrm{a}, i)$. Rules however, need to satisfy a constraint related to sites: if an edge exists for a site in either sides of a rule, then it exists in both sides.
Definition 5 (Double-pushout rewriting [?]). Let $\vec{r}=L \stackrel{p}{\leftarrow} K \xrightarrow{q} R$ be a rule. Let $M$ be a site-graph (typically a system state) and let $m: L \rightarrow M$ be a mono, called a matching. The double pushout rewriting consists in defining the site-graph $D$, called the context graph, and the site-graph $N$ such that the two squares in diagram DPO are pushouts. We refer to the dpo rewrite of $M$ to $N$ as $M \stackrel{m \vec{r}}{\Rightarrow} N$ and denote the state transition associated with the application of rule $\vec{r}=\langle p, q\rangle$ at "location" $m$ of the system state $M$ (i.e. the mixture) as $\operatorname{mix}(M \stackrel{m \vec{r}}{\Rightarrow} N)=M \leftarrow D \rightarrow N$.

Given the definition above, a context graph $D$ need not always exist. We use dpo rewriting for the sake of simplicity, but our work extends to other graph rewriting techniques.

### 2.3 Influence

The postcondition resulting from the application of a rule $\overrightarrow{r_{1}}$ can satisfy or, more generally, contribute (in conjunction with other rules) to satisfying the precondition for the application of another rule $\overrightarrow{r_{2}}$. Alternatively, $\overrightarrow{r_{1}}$ might destroy the precondition of $\overrightarrow{r_{2}}$. In the former case we speak of a positive influence of $\overrightarrow{r_{1}}$ on $\overrightarrow{r_{2}}$ and, in the latter case, of a negative influence. Of course, a rule may also have no influence on a particular other rule.

Influenc ${ }^{3}$ belongs to the realm of possibility: it is a latent relation between rules that becomes manifest as a relation between events (i.e. actual rule applications) in the specific context of a trace, as we discuss formally in Section 3 .

We next define two categorical concepts needed for capturing influence. Multisums are meant to characterize all possible ways of gluing together two graphs $G_{1}$ and $G_{2}$.
Definition 6 (Multisum in the subcategory of monos [?]). Let $G_{1}$ and $G_{2}$ be two graphs. The multisum of $G_{1}$ and $G_{2}$, denoted with multisum $\left(G_{1}, G_{2}\right)$, is a family of cospans of monos $\vec{f}_{i}=\left\langle f_{1, i}, f_{2, i}\right\rangle$, with $f_{j, i}: G_{j} \rightarrow M_{i}, i \leq n, j \in\{1,2\}$, such that for any other cospan of monos $\overrightarrow{f^{\prime}}$, with $f_{j}^{\prime}: G_{j} \rightarrow M^{\prime}$, there exists an $M_{k}, k \leq n$ and a unique mono $M_{k} \rightarrow M^{\prime}$ that makes diagram MS below commute. Moreover, for any monos $M_{k} \rightarrow M^{\prime}$ and $M_{i} \rightarrow M^{\prime}, i, k \leq n$, for which diagram MS commutes, we have $M_{k} \cong M_{i}$.

Unlike other constructions, which are defined in $\mathscr{G}$, multisums are defined in the subcategory of $\mathscr{G}$ whose morphisms are restricted to monos. Multisums always exists in this subcategory.
Definition 7 (Pullback). The pullback of the cospan $\vec{f}$ consists of a span $\vec{g}$ such that $f_{1} g_{1}=f_{2} g_{2}$. In addition, for any other span $\overrightarrow{g^{\prime}}$ such that $f_{1} g_{1}^{\prime}=f_{2} g_{2}^{\prime}$, there is a unique morphism $O^{\prime} \rightarrow O$ that makes diagram PB commute.

[^2]

The pullback always exists in $\mathscr{G}$. Using these notions we can define influence.
Definition 8 (Positive influence [?]). Given two rules $\overrightarrow{r_{1}}=L_{1} \leftarrow K_{1} \xrightarrow{i} R_{1}$ and $\overrightarrow{r_{2}}=L_{2} \leftarrow K_{2} \rightarrow R_{2}$, consider an overlap between $R_{1}$ and $L_{2}$, i.e. a cospan $\vec{f} \in$ multisum $\left(R_{1}, L_{2}\right)$, and let $\vec{g}$ be the pullback of $\vec{f}$. Moreover, let $\vec{h}$ be the pullback of $\left\langle i, g_{1}\right\rangle$. The rule $\overrightarrow{r_{1}}$ has a positive influence on rule $\overrightarrow{r_{2}}$, if $h_{2}$ is not an iso. In other words, if $O$ is not contained in $P$ and, thus, in $K_{1}$. The influence is induced by the overlap $\vec{g}$ corresponding to $\vec{f}$ and is denoted by $\overrightarrow{r_{1}} \xrightarrow{+\vec{g}} \overrightarrow{r_{2}}$.

The diagram on the right depicts the relationships used in Definition 8. The rule $\overrightarrow{r_{1}}$ has a positive influence on $\overrightarrow{r_{2}}$ if it creates a subgraph of $L_{2}$. By requiring $h_{2}$ not to be an iso, we assert that $O$ is not already present in $L_{1}$ and must, therefore, be produced by $\overrightarrow{r_{1}}$. Negative influence $\overrightarrow{r_{1}} \xrightarrow{-\vec{g}} \overrightarrow{r_{2}}$ is defined analogously, but with $\vec{g}$
 now the pullback of a cospan $\vec{f} \in$ multisum $\left(L_{1}, L_{2}\right)$ between the left hand sides: $\overrightarrow{r_{1}}$ has a negative influence on $\overrightarrow{r_{2}}$, if it destroys a subgraph of $L_{2}$.

Example 1. The rule $\overrightarrow{r_{1}}$ has a positive influence on $\overrightarrow{r_{2}}$, because $\overrightarrow{r_{1}}$ produces an agent $B$ needed for a subsequent application of $\overrightarrow{r_{2}}$ shown in Figure 4. Similarly $\overrightarrow{r_{2}}$ has a negative influence on $\overrightarrow{r_{1}}$ since it erases an agent A needed by $\overrightarrow{r_{1}}$.

Figure 4: Positive influence between two rules. For simplicity, sites are omitted.

### 2.4 Transition systems

Following Refs. [?, ?] we introduce the notion of transition system (TS) on state graphs and an independence relation between transitions. We then propose new relations of enablement and prevention between transitions, based on the notions of rule influence just defined, and connect them to independence.
Definition 9 (TS on graphs [?]). A transition system $T S=(Q, \mathscr{R}, T)$ on graphs consists of:

- a set of states $Q \subseteq \mathscr{G}$, where each state is a graph;
- a set of rules $\mathscr{R}$;
- a set of labeled transitions $T \subseteq Q \times \operatorname{hom}(\mathscr{G}) \times \mathscr{R} \times Q$, where each transition $t$ is a dpo rewriting step $M \stackrel{m \vec{r}}{\Rightarrow} N$ with $M, N \in Q$, an underlying rule $\vec{r}: L \leftarrow K \rightarrow R \in \mathscr{R}$, and a matching $m: L \rightarrow$ $M \in \operatorname{hom}(\mathscr{G})$.

Transitions can be composed $t_{1} ; t_{2}$ if the source state of $t_{2}$ matches the destination state of $t_{1}$. A trace $\theta$ is a (possibly empty) sequence of composable transitions: $\theta=t_{1} ; t_{2} ; \cdots ; t_{n}$.
Definition 10 (Independence relation on transitions [?]). Let $t_{1}: M \stackrel{m_{1}, \overrightarrow{r_{1}}}{\Rightarrow} M_{1}, t_{2}: M_{1} \stackrel{m_{2}, \vec{r}_{2}}{\Rightarrow} M_{2}$ and $t_{3}$ : $M \stackrel{m_{3}, \overrightarrow{r_{r}}}{\Rightarrow} M_{3}$ be transitions with underlying rules $\overrightarrow{r_{i}}=L_{i} \leftarrow K_{i} \rightarrow R_{i} \in \mathscr{R}, i \in\{1,2,3\}$ and corresponding matchings $m_{i}$ as indicated in the diagrams below.
sequential independence $t_{1}$ and $t_{2}$ are sequentially independent, written $t_{1} \diamond_{\text {seq }} t_{2}$, iff there exist morphisms $i: R_{1} \rightarrow D_{2}$ and $j: L_{2} \rightarrow D_{1}$ such that $f_{2} i=n_{1}$ and $g_{1} j=m_{2}$.
parallel independence $t_{1}$ and $t_{3}$ are parallel independent, written $t_{1} \diamond_{\text {par }} t_{3}$, iff there exist morphisms $i: L_{1} \rightarrow D_{3}$ and $j: L_{3} \rightarrow D_{1}$ such that $f_{3} i=m_{1}$ and $f_{1} j=m_{3}$.

sequential independence

parallel independence

In the following, we use the function mix (of Definition 5) to chain transitions by span composition (see diagrams below). Given two spans $\vec{f}=\left\langle f_{1}, f_{2}\right\rangle$ and $\vec{g}=\left\langle g_{1}, g_{2}\right\rangle$, we define their composition as $\vec{g} \vec{f}=\left\langle f_{1} h_{1}, g_{2} h_{2}\right\rangle$ where $\vec{h}$ is the pullback of $\left\langle f_{2}, g_{1}\right\rangle$. A partial morphism $f: M_{1} \rightharpoonup M_{3}$ is a total morphism from the subgraph $\operatorname{dom}(f)$ of $M_{1}$ to $M_{3}$, that is $f: M_{1} \supseteq \operatorname{dom}(f) \rightarrow M_{3}$. Given a span $M_{1} \stackrel{l}{\leftarrow}$ $D \xrightarrow{r} M_{3}$, its corresponding partial morphism, denoted $M_{1} \rightharpoonup M_{3}$, is defined on $l(D)$ as $l^{-1} r$ and undefined otherwise [?].

$$
M_{1} \stackrel{f_{1}}{\leftrightarrows} D_{1} \underset{h_{1}}{\stackrel{f_{2}}{\leftrightarrows}} M_{2} \underset{D}{\stackrel{g_{1}}{h_{2}}} D_{2} \stackrel{g_{2}}{\longrightarrow} M_{3} \quad M_{1} \stackrel{l}{\leftrightarrows} D \xrightarrow{r} M_{3}
$$

Definition 11 (Causality). Let $t_{1}: M_{1} \stackrel{m_{1}, \vec{r}_{1}}{\Rightarrow} N_{1}$ and $t_{2}: M_{2} \stackrel{m_{2}, \overrightarrow{r_{2}}}{\Rightarrow} N_{2}$ be two transitions bracketing a trace $\theta: t_{1} ; t_{1}^{\prime} ; t_{2}^{\prime} ; \cdots ; t_{n}^{\prime} ; t_{2}$. The rules inducing $t_{i}, i \in\{1,2\}$, are $\vec{r}_{i}=L_{i} \leftarrow K_{i} \rightarrow R_{i}$ with matchings $m_{i} \in \operatorname{hom}(\mathscr{G})$ into $M_{1}$ and $M_{2}$, respectively.
enablement Let $\vec{g}$ be a span such that $\overrightarrow{r_{1}} \xrightarrow{+\vec{g}} \overrightarrow{r_{2}}$. If the diagram below on the left commutes then $t_{1}$ enables $t_{2}$, denoted $t_{1}<_{\theta} t_{2}$. In the diagram below on the left, the partial morphism $N_{1} \rightharpoonup M_{2}$ is obtained from the composition of $\operatorname{mix}\left(t_{1}^{\prime}\right) \circ \cdots \circ \operatorname{mix}\left(t_{n}^{\prime}\right)$.
prevention Let $\vec{g}$ be a span such that $\overrightarrow{r_{2}} \xrightarrow{-\vec{g}} \overrightarrow{r_{1}}$. If the diagram below on the right commutes then $t_{2}$ prevents $t_{1}$, denoted $t_{2} \dashv_{\theta} t_{1}$. In the diagram below on the right the partial morphism $M_{1} \rightharpoonup M_{2}$ is the composition of $\operatorname{mix}\left(t_{1}\right) \circ \operatorname{mix}\left(t_{1}^{\prime}\right) \circ \cdots \circ \operatorname{mix}\left(t_{n}^{\prime}\right)$.

enablement

prevention

To make the underlying span explicit, we sometimes write $\left(t_{1}, t_{2}, \vec{g}\right) \in<_{\theta}$ and $\left(t_{1}, t_{2}, \vec{g}\right) \in \dashv_{\theta}$.

Figure 5: Transition $t_{2}$ binds agents A and D , needed by transition $t_{4}$. Transition $t_{3}$ needs to happens between the two, as it (i) binds agents A and B as needed by $t_{4}$ and (ii) unbind A from C which was necessary for $t_{2}$.

Example 2. Consider the trace of Figure 5. The first transition enables the second and third transitions. The second transition enables the last transition. However, it is a "delayed" enabler: it partially fulfills the precondition of the last transition, but the third transition has to happen before. Note that such type of causality is not captured by the graph rewriting framework of [?, ?, ? $]^{4}$. Lastly note that the third transition is a preventer for the second one.

## 3 Posets of graph rewriting events

In this section we abstract a trace into a poset of events, and concretize a poset back into a set of traces. Each transition becomes an event in a poset with the underlying rule as its label. Similarly, in the concretization, each event in a poset corresponds to a transition such that transitions compose into a trace. The abstraction is used to reduce the number of simulation traces to a small set of posets, and the concretization recomputes a "representative" trace from each poset. Concretized traces are used in the next section.

### 3.1 From traces to posets

A transition $t$ (Definition 5 ) is a pair of spans-mix $(t)=M \leftarrow D \rightarrow N$ and the underlying rule $\vec{r}: L \leftarrow$ $K \rightarrow R$-and a matching $m: L \rightarrow M$. When abstracting a trace into a partial order, we drop the span $\operatorname{mix}(t)$ and $m$. The enabling and prevention relations between transitions in a trace (Section 2.4) translate into a partial order on events, labeled by the underlying rules.

We proceed in two steps. Enabling and prevention between transitions hinge on positive and negative influence between the underlying rules (see Definition (11). Recall that when transition $t$ enables transition $t^{\prime}$ within a trace $\theta$ there exists a span $\vec{f}$ for which $\left(t, t^{\prime}, \vec{f}\right) \in<_{\theta}$. The first abstraction, $\mathscr{A}_{1}$, forgets the matching and the span $\operatorname{mix}(t)$ of a transition $t$, but preserves enablement and prevention relations between transitions and the positive and negative influence between the underlying rules.
Definition 12 (Abstraction step 1). Let $\theta=t_{1} ; t_{2} ; \cdots ; t_{n}$ be a trace and $E=\left\{e_{1}, e_{2}, \cdots, e_{n}\right\}^{5}$ be a set of events. Events are labeled using a function $\ell: E \rightarrow \mathscr{R}$ such that $\ell\left(e_{i}\right)=r_{i}$ if $t_{i}: M_{i} \stackrel{m_{i}, \vec{r}_{i}}{\Rightarrow} N_{i}$, for $i \leq n$. We then define two relations $\cdot \xrightarrow{+\cdot} \cdot, \cdot \xrightarrow{-\longrightarrow} \subseteq E \times E \times \operatorname{span}(\mathscr{G})$ :

[^3]$$
e_{i} \xrightarrow{+\vec{f}} e_{j} \Longleftrightarrow\left(t_{i}, t_{j}, \vec{f}\right) \in<_{\theta} \text { and } e_{i} \xrightarrow{-\vec{f}} e_{j} \Longleftrightarrow\left(t_{i}, t_{j}, \vec{f}\right) \in \dashv_{\theta},
$$
for $e_{i}, e_{j} \in E, i, j \leq n$ and $\vec{f} \in \operatorname{span}(\mathscr{G})$. We denote this first abstraction of $\theta$ with $\mathscr{A}_{1}(\theta)=(E, \ell, \stackrel{+}{\rightarrow}, \stackrel{\rightarrow}{\rightarrow})$.
The notation $e \xrightarrow{+\vec{f}} e^{\prime}$, for some span $\vec{f}$, overloads the notation $\ell(e) \xrightarrow{+\vec{f}} \ell\left(e^{\prime}\right)$. Keep in mind, however, that the first is defined on events whereas the second can be inferred from the rules on which it holds (see Definition (8).

In the second abstraction step, $\mathscr{A}_{2}$, we map the relations $\xrightarrow{+}$ and $\xrightarrow{-}$ to corresponding partial orders on events. This step simply forgets the spans responsible for the enablement and prevention relations on transitions.
Definition 13 (Abstraction step 2). Let $E$ be a set of events equipped with a labeling function $\ell: E \rightarrow \mathscr{R}$ and two relations $\cdot \xrightarrow{+\cdot} \cdot, \xrightarrow{-\bullet} \cdot \subseteq E \times E \times \operatorname{span}(\mathscr{G})$. We translate the relations on events from Definition 12 into two new relations $<, \| \subseteq E \times E$ :

$$
\begin{aligned}
& e_{i}<e_{j} \Longleftrightarrow e_{i} \xrightarrow{+\vec{f}} e_{j} \text { and } e_{i} \Vdash e_{j} \Longleftrightarrow e_{j} \xrightarrow{-\vec{f}} e_{i} .
\end{aligned}
$$

The associated poset is defined as $\mathscr{A}_{2}(E, \ell, \xrightarrow{+} \xrightarrow{-})=(E, \ell, \leq, \vdash)$, where $\leq$ and $\vdash$ are the transitive and reflexive closure of $<$ and $\Vdash$, respectively. We call the two relations $\leq$ and $\vdash$, (enabling) precedence and non-enabling precedence, respectively $\sqrt{6}$
Lemma 1. Let $\theta$ be a trace and let $e, e^{\prime} \in E$ be two events with $\mathscr{A}_{2} \mathscr{A}_{1}(\theta)=(E, \ell, \leq, \vdash)$. If $e<e^{\prime}$ then there exists a span $\vec{f}$ such that $\ell(e) \xrightarrow{+\vec{f}} \ell\left(e^{\prime}\right)$. Similarly, if $e \Vdash e^{\prime}$, then there exists a span $\vec{f} \in \operatorname{span}(\mathscr{G})$ such that $\ell\left(e^{\prime}\right) \xrightarrow{-\vec{f}} \ell(e)$.

A morphism on posets is a function on events that preserves labels and the two precedence relations. An isomorphism between two posets $s_{1}$ and $s_{2}$ is denoted by $s_{1} \cong s_{2}$. For a set of traces $\Theta=\left\{\theta_{1}, \cdots, \theta_{n}\right\}$, we write $\mathscr{S}=\left(s_{1}, \cdots, s_{k}\right) / \cong$ with $k \leq n$ for the set of posets obtained via $\mathscr{A}_{2} \mathscr{A}_{1}$ and quotiented by iso.
Example 3. Consider the trace $\theta=t_{1} ; t_{2} ; t_{3} ; t_{4}$ of Example 2. The corresponding poset consists of the events $\left\{e_{1}, e_{2}, e_{3}, e_{4}\right\}$ with the relations $<=\left\{\left(e_{1}, e_{2}\right) ;\left(e_{1}, e_{3}\right) ;\left(e_{2}, e_{4}\right) ;\left(e_{3}, e_{4}\right)\right\}$ and $\Vdash=\left\{\left(e_{2}, e_{3}\right)\right\}$. Note that $e_{2}$ is a non-enabling precedent of $e_{3}$, as in the original trace transition $t_{3}$ prevents transition $t_{2}$.

### 3.2 From posets to traces

We next specify the concretization from posets to traces. Again, we proceed in two steps. The first concretization retrieves the intermediate structure $(E, \ell \xrightarrow{+} \xrightarrow{\hookrightarrow})$ from a poset $(E, \ell, \leq, \vdash)$. This step recovers the influence (positive or negative) between the rules underlying two events that are in a particular precedence or non-enabling precedence relation.
Definition 14 (Concretization step 1). Let $(E, \ell, \leq, \vdash)$ be a poset. We define the relations $\xrightarrow{+}, \stackrel{\hookrightarrow}{\subseteq}$ $E \times E \times \operatorname{span}(\mathscr{G})$ as follows:

- $e_{i} \xrightarrow{+\vec{f}} e_{j} \Longleftrightarrow \ell\left(e_{i}\right) \xrightarrow{+\vec{f}} \ell\left(e_{j}\right)$ and $e_{i}<e_{j}$, for some $\vec{f} \in \operatorname{span}(\mathscr{G}) ;$
- $e_{i} \xrightarrow{-\vec{f}} e_{j} \Longleftrightarrow \ell\left(e_{i}\right) \xrightarrow{-\vec{f}} \ell\left(e_{j}\right)$ and $e_{j} \Vdash e_{i}$, for some $\vec{f} \in \operatorname{span}(\mathscr{G})$

[^4]where $<$ and $\Vdash$ are the reduced relation of $\leq$ and $\vdash$, respectively. The concretization of a poset is then $\mathscr{C}_{1}(E, \ell, \leq, \vdash)=(E, \ell, \xrightarrow{\rightarrow}, \stackrel{-}{\rightarrow})$.
Example 4. Consider a poset of events $e_{1}, e_{2}$ and $e_{3}$ with labels $\overrightarrow{r_{1}}, \overrightarrow{r_{2}}$ and $\overrightarrow{r_{3}}$, respectively, as shown in Figure 6. Furthermore, suppose that events $e_{1}$ and $e_{2}$ both precede $e_{3}$. For the pair $e_{1}<e_{3}$, one can infer the positive influence $\overrightarrow{r_{1}} \xrightarrow{+\vec{f}} \overrightarrow{r_{3}}$. For the pair $e_{2}<e_{3}$, we need to consider two possibilities: either

Figure 6: All possible influences between three rules.
$\overrightarrow{r_{2}} \xrightarrow{+\vec{g}} \overrightarrow{r_{3}}$ or $\overrightarrow{r_{2}} \xrightarrow{+\vec{h}} \overrightarrow{r_{3}}$. The relation induced by the span $\vec{g}$ is problematic. Intuitively, the events $e_{1}$ and $e_{2}$ should produce a distinct set of agents for event $e_{3}$. Specifically, both cannot produce the same agent A that binds to B in $e_{3}$. The consistent span attributes the creation of agent A to $e_{1}$ and the creation of B to $e_{2}$ (in addition to a further A not used in $e_{3}$ ). In this manner, both $e_{1}$ and $e_{2}$ are necessary for the occurence of $e_{3}$.

As the example indicates, it is not trivial to retrieve the influence between events from the influence between rules. The problem is that influence between events is a global property of the poset, whereas influence between rules is local to the two rules. Lack of space prevents us from characterizing the correct concretizations of a poset. Informally, a concretization of a poset $s$ is correct if (i) every relation on events in $s$ is due to a shared resource (i.e. an agent or an edge) and if (ii) every resource in $s$ is consistent throughout $s$.

The second concretization maps events into transitions such that: (i) the transitions compose into a valid trace and (ii) the relations defined on the events hold on the transitions of the trace. We call a candidate for concretization any function from events to transitions that satisfies condition (i).
Definition 15. Let $E$ be a set of events with a labeling function $\ell: E \rightarrow \mathscr{R}$ and a total order on events $\sqsubset \subseteq E \times E$. A function concrete : $E \rightarrow T$ is called a candidate for concretization if concrete $(e)=M \stackrel{m, \vec{r}}{\Rightarrow} N$ such that $\ell(e)=\vec{r}$, for some graphs $M, N$, and a morphism $m$. Moreover concrete $\left(e_{1}\right) ; \cdots ;$ concrete $\left(e_{n}\right)$, with $e_{i} \sqsubset e_{i+1}, i \leq n$, compose into a trace.

Any such function must also satisfy condition (ii), as in the following definition.
Definition 16 (Concretization step 2). Let $E$ be a set of events equipped with a function $\ell: E \rightarrow \mathscr{R}$ and two relations $\cdot \xrightarrow{+\cdot} \cdot, \xrightarrow{--} \cdot \subseteq E \times E \times \operatorname{span}(\mathscr{G})$. Let $\sqsubset$ be a total order on events and let concrete : $E \rightarrow T$ be a function from events to transitions such that the following hold:

$$
\begin{aligned}
& \text { - }\left(t_{i}, t_{j}, \vec{f}\right) \in<_{\theta} \Longleftrightarrow e_{i} \xrightarrow{+\vec{f}} e_{j} \text { and } \\
& \text { - }\left(t_{i}, t_{j}, \vec{f}\right) \in \dashv_{\theta} \Longleftrightarrow e_{i} \xrightarrow{-\vec{f}} e_{j}
\end{aligned}
$$

for $e_{i}, e_{j} \in E, i, j \leq n$. Then the concretized trace is $\mathscr{C}_{2}(E, \ell, \xrightarrow{+}, \xrightarrow{-}$, concrete, $\sqsubset)=\operatorname{concrete}\left(e_{1}\right) ; \cdots$; concrete $\left(e_{n}\right)$, for $e_{i} \sqsubset e_{i+1}, i \leq n$.

For $(E, \ell, \leq, \dashv)$ a poset, we write $\mathscr{C}(E, \ell, \leq, \dashv)$ for the set of all possible concretisations, i.e. the set of all traces $\theta$ as specified by $\mathscr{C}_{1}(E, \ell, \leq, \dashv)$ and $\mathscr{C}_{2}(E, \ell \xrightarrow{+}, \xrightarrow{-}$, concrete, ᄃ). We write $(\theta$, concrete $) \in$ $\mathscr{C}(E, \ell, \leq, \dashv)$ for the concretization function used in reconstructing a particular $\theta$.
Theorem 1. Let $\theta$ be a trace. Then $\theta \in \mathscr{C} \mathscr{A}_{2} \mathscr{A}_{1}(\theta)$. Moreover, for any trace $\theta^{\prime} \in \mathscr{C} \mathscr{A}_{2} \mathscr{A}_{1}(\theta)$, $\mathscr{A}_{2} \mathscr{A}_{1}(\theta) \cong \mathscr{A}_{2} \mathscr{A}_{1}\left(\theta^{\prime}\right)$.

## 4 A logic on posets

In Figure 7 we define a fragment of a first order logic that can be used to express assertions about positive and negative influence between mechanisms, that is, posets. We interpret the logic on the set of posets $\mathscr{S}$, ranged over by $s$, and on the set of events $\mathscr{E}=\cup_{s_{i} \in S} E_{s_{i}}$, where $E_{s_{i}}$ is the set of events in $s_{i}$. To distinguish between the partial orders of different posets in $\mathscr{S}$, we write $s=$ $\left(E_{s}, \leq_{s}, \vdash_{s}, \ell_{s}\right)$. In the following, $x$ stands for variables, $t$ for terms and the superscripts $e$ and $s$ indicate whether the variables and

$$
\begin{array}{rrr}
x::=x^{e} \mid x^{s} & \text { (variables on events and posets) } \\
t^{s}::=x^{s} \mid s & \text { (terms on posets) } \\
t^{e}::=x^{e} \mid e & \text { (terms on events) } \\
t::=t^{s} \mid t^{e} & \text { (terms) } \\
\varphi::=\exists x . \varphi(x)|\forall x . \varphi(x)| & \text { (quantifiers) } \\
& \neg \varphi\left|\varphi_{1} \wedge \varphi_{2}\right| & \text { (logical connectors) } \\
& t^{e} \in t^{s}\left|\ell\left(t^{e}\right)=\vec{r}\right| t_{1}^{e} \leq_{t^{s}} t_{2}^{e} \mid t_{1}^{e} \vdash_{t^{s}} t_{2}^{e} & \\
& \left|t_{1}^{e} \in t_{1}^{s} \leadsto t_{2}^{e} \in t_{2}^{s}\right| t_{1}^{e} \in t_{1}^{s} \stackrel{+}{\leftrightarrows} t_{2}^{e} \in t_{2}^{s} & \text { (predicates) }
\end{array}
$$ terms range over events or posets, respectively. Formulas are denoted by $\varphi$ and are built from predicates on variables and terms.

A valuation for $\varphi$ is a function $v: \mathrm{fv}(\varphi) \rightarrow \mathscr{E} \uplus \mathscr{S}$ from the set of free variables of $\varphi$ to the set of events and posets. The evaluation of $\varphi$ is defined below and requires a valuation function $v$ for the set of free variables of $\varphi$; the evaluation is therefore parametric on $v$. We use two functions, one to evaluate terms $\left\}_{v}: t \rightarrow \mathscr{E} \uplus \mathscr{S} \text { and one to evaluate formulas }[]\right]_{v}: \varphi \rightarrow\{T, F\}$. A formula $\varphi$ is satisfiable if there exists $v$ such that $\llbracket \varphi \rrbracket_{v}$ evaluates to true. The interpretation of formulas and terms is shown in Figure 8 .

$$
\begin{aligned}
& \llbracket \forall x^{s} \cdot \varphi \rrbracket_{v} \Longleftrightarrow \text { for all } s \in \mathscr{S}, \llbracket \varphi(s / x) \rrbracket_{v} \\
& \llbracket \exists x^{s} \cdot \varphi \rrbracket_{v} \Longleftrightarrow \text { for some } s \in \mathscr{S}, \llbracket \varphi(s / x) \rrbracket_{v} \\
& \llbracket \neg \varphi \rrbracket_{v}=\neg \llbracket \varphi \rrbracket_{v} \\
& \llbracket \varphi_{1} \wedge \varphi_{2} \rrbracket_{v}=\llbracket \varphi_{1} \rrbracket_{v} \wedge \llbracket \varphi_{2} \rrbracket_{v} \\
& \llbracket t^{e} \in t^{s} \rrbracket_{v} \Longleftrightarrow\left\{t^{e}\right\}_{v} \in\left\{t^{s}\right\}_{v} \\
& \llbracket \ell\left(t^{e}\right)=\vec{r} \rrbracket_{v} \Longleftrightarrow \ell\left(\left\{t^{e}\right\}_{v}\right)=\vec{r} \\
& \llbracket t_{1}^{e} \leq_{t^{s}} e_{2}^{e} \rrbracket_{v} \Longleftrightarrow e_{1} \leq_{s} e_{2} \text { where } e_{1}=\left\{t_{1}^{e}\right\}_{v}, e_{2}=\left\{t_{2}^{e}\right\}_{v}, s=\left\{t^{s}\right\}_{v} \\
& \llbracket t_{1}^{e} \vdash_{t^{s}} t_{2}^{e} \rrbracket_{v} \Longleftrightarrow e_{1} \vdash_{s} e_{2} \text { where } e_{1}=\left\{t_{1}^{e}\right\}_{v}, e_{2}=\left\{t_{2}^{e}\right\}_{v}, s=\left\{t^{s}\right\}_{v} \\
& \llbracket t_{1}^{e} \in t_{1}^{s} \stackrel{/-}{\sim} t_{2}^{e} \in t_{2}^{s} \rrbracket_{v} \Longleftrightarrow e_{1} \in s_{1} \stackrel{+/-}{\sim} e_{2} \in s_{2} \text { where } e_{1}=\left\{t_{1}^{e}\right\}_{v}, e_{2}=\left\{t_{2}^{e}\right\}_{v}, \\
& s_{1}=\left\{t_{1}^{s}\right\}_{v}, s_{2}=\left\{t_{2}^{s}\right\}_{v} \\
&\{x\}_{v}=v(x) \\
&\{e\}_{v}=e \\
&\{s\}_{v}=s
\end{aligned}
$$

Example 5. We return to the introductory example. The mechanisms of binding an agent A to an agent X or to an agent Y consist in the application of rule $\overrightarrow{r_{\mathrm{AX}}}$ and $\overrightarrow{r_{\mathrm{AY}}}$, respectively. The assertion that the first mechanism prevents (or conflicts with) the second is written as $\exists e_{1} .\left(e_{1} \in s_{1} \wedge \ell\left(e_{1}\right)=\overrightarrow{r_{\mathrm{AX}}}\right) \wedge \exists e_{2} .\left(e_{2} \in\right.$ $\left.s_{2} \wedge \ell\left(e_{2}\right)=\overrightarrow{r_{\mathrm{AY}}}\right) \wedge e_{1} \in s_{1} \leadsto e_{2} \in s_{2}$. The logic allows us to formulate more complex mechanisms. For our example, we can write $\exists e . e \in s \wedge \ell(e)=\overrightarrow{\mathrm{AX}} \vee \ell(e)=r_{\mathrm{AY}}$ for a mechanism that produces A bound to either X or Y .

The predicates $e_{1} \in s_{1} \stackrel{+}{\sim} e_{2} \in s_{2}$ and $e_{1} \in s_{1} \leadsto e_{2} \in s_{2}$ check for enablement and prevention between two posets. Informally, $e_{1}$ and $e_{2}$ represent the "meeting point" of the two posets $s_{1}$ and $s_{2}$. We use these events to reconstruct a graph that represents a context in which $s_{1}$ enables or prevents $s_{2}$.

The causal past of an event is the set of events that preceded it. We denote with $[e]_{s}$ the causal past of an event $e \in E_{s}$ and define $[e]_{s}=\left(E^{\prime}, \leq^{\prime}, \vdash^{\prime}, \ell^{\prime}\right)$ with $E^{\prime}=\left\{e^{\prime}: e^{\prime} \in E, e^{\prime} \leq e\right\}$ and $\leq^{\prime}, \vdash^{\prime}, \ell^{\prime}$ defined like $\leq, \vdash, \ell$ but restricted to $E^{\prime}$.

Definition 17 (Occurrence context of an event in a poset). Let $s$ be a poset and let $e \in E_{s}$ be an event. Furthermore, let $(\theta$, concrete $) \in \mathscr{C}\left([e]_{s}\right)$ be a concretization of $[e]_{s}$. We say that a morphism $m$ is an occurrence context of e in $s$ if concrete $(e)=M \stackrel{m \ell(e)}{\Rightarrow} N$, for some graphs $M, N$.

The occurrence context of $e_{1}$ in $s_{1}$ and of $e_{2}$ in $s_{2}$ is specified by matchings $m_{1}: L_{1} \rightarrow M_{1}$ and $m_{2}: L_{2} \rightarrow M_{2}$, respectively. The diagram on the right illustrates the prevention of $s_{2}$ by $s_{1}$. Since the graph $M$ contains both $M_{1}$ and $M_{2}$, both events $e_{1}$ and $e_{2}$ can occur in that context. We then say that $M$ is a scenario for the prevention of $s_{2}$ by $s_{1}$, which is induced by a negative influence between the underlying rules, $\ell\left(e_{1}\right) \xrightarrow{-\vec{f}} \ell\left(e_{2}\right)$. The scenario graph $M$ is formally defined as follows.
Definition 18 (Scenario for prevention). Let $m_{i}$ be an occurrence context of event $e_{i}$ in the poset $s_{i}$, $i \in\{1,2\}$. Let $\vec{f}$ be a span such that $\ell\left(e_{1}\right) \xrightarrow{-\vec{f}} \ell\left(e_{2}\right)$. Define the span $\vec{g}=\left\langle g_{1}, g_{2}\right\rangle$ as $g_{i}=m_{i} f_{i}, i \in\{1,2\}$. We say that the graph $M$ obtained by the pushout $\vec{g}$ is a scenario (graph) for the prevention of $e_{2} \in s_{2}$ by $e_{1} \in s_{1}$.
Example 6. Let $L_{1}, L_{2}$ be the left hand sides of rules $r_{\mathrm{AX}}$ and $r_{\mathrm{AY}}$ from Figure 2. We have a negative influence between the rules $r_{\mathrm{AX}}$ and $r_{\mathrm{AY}}$ induced by the agent A . The occurence context of $e_{\mathrm{AX}}$ in the poset AX is obtained from the concretization of the poset AX and consists of the morphism $L_{1} \rightarrow G_{\mathrm{AX}}$. Similarly the occurence context of $e_{\mathrm{AY}}$ in the poset AY is $L_{2} \rightarrow G_{\mathrm{AY}}$. There is no scenario for prevention as the graph $G$ (in Figure 2) is not a site-graph.

In a similar manner we interpret the enabling relation between two mechanisms. The predicate $\left(e_{1} \in s_{1} \xrightarrow{+/-} e_{2} \in s_{2}\right)$ returns true if there exists a scenario $M$ as defined above. The pushout does not always exists and, in consequence, mechanisms do not always interact with one another.

The logic is implemented as a systematic inspection of each poset. The set of posets does not have in itself a structure, and therefore there is no smart strategy for deciding whether a formula holds. The point of the logic is to give a formal language and an interpretation for influence between posets.
Example 7. Let us look at a Kappa model slightly more complicated than the one in the Introduction. We give the rules in the figure below. The two posets build up the graphs $G_{\mathrm{AX}}$ and $G_{\mathrm{AY}}$. Then there are two "resources" which can produce an inhibition between the two posets. They produce two scenario graphs for inhibition $G_{1}$ and $G_{2}$, shown in Figure 9 .

Figure 9: A Kappa model for which there are two scenarios for the prevention between the events labeled $r_{\mathrm{AX}}$ and $r_{\mathrm{AY}}$.

Figure 10: A slightly different Kappa model for which only one of the scenarios is still valid.

Let us change rule $r_{\mathrm{AB}}^{\prime}$ into $r_{\mathrm{AB}}^{\prime \prime}$ and keep everything else the same. With the new rule the graph build up by Poset AX requires the site 2 of agent $C$ to be free. In this case only one scenario for inhibition can still occur, shown in Figure 10.

## 5 Conclusions

Given a categorical notion of graph rewrite system, we defined positive and negative influence between rules. This allowed us to define sequential and parallel independence between state transitions and the relations of enablement and prevention. These were then lifted to the poset abstraction of a trace of state transitions, where they became enabling and non-enabling precedence relations within a poset. The formulation of a logic on posets then allows us to formulate questions about enablement and prevention relations between posets. We ended by specifying how the concretization of posets back into a trace provides a scenario graph that establishes the truth (or falsity) of a statement about poset interaction. These notions, together with their implementation, are meant to assist a modeler in checking the consistency between observations and the mechanisms that are implied by a rule-based model.

Acknowledgements. We gratefully acknowledge illuminating discussions with Russ Harmer, Jerome Feret, and Jonathan Laurent. Special thanks to Pierre Boutillier for his help in developing and integrating the model checker resulting from this contribution into the Kappa software framework.

## A Appendix

In this appendix we present the proofs missing in our presentation as well as providing more examples and remarks.

## A. 1 Another Example

Let us look at a Kappa model slightly more complicated than the one in the Introduction. We give the rules in the figure below. The two posets build up the graphs $G_{\mathrm{AX}}$ and $G_{\mathrm{AY}}$. Then there are two "resources" which can produce an inhibition between the two posets. They produce two scenario graphs for inhibition $G_{1}$ and $G_{2}$, shown below.

Let us change rule $r_{\mathrm{AB}}^{\prime}$ into $r_{\mathrm{AB}}^{\prime \prime}$ and keep everything else the same. With the new rule the graph build up by Poset AX requires the site 2 of agent $C$ to be free. In this case only one scenario for inhibition can still occur, shown below.

## A. 2 Proofs of Section 2.1

Lemma 2. Site-graphs and their morphisms form a category.
Proof. The category of site-graphs has as objects the site-graphs of 1 and as arrows the morphisms of 2 . Let us show morphisms compose. Given three site-graphs $G_{1}, G_{2}, G_{3}$ and two morphisms $f: G_{1} \rightarrow G_{2}$, $g: G_{2} \rightarrow G_{3}$ let $h=g f$ be the (pairwise) composition of the two. It follows

- for an agent $\mathrm{a} \in \mathscr{A}_{G_{1}}$, type $(h(\mathrm{a}))=g(f(\operatorname{type}(\mathrm{a}))$ and we have that type $(h(\mathrm{a}))=h(\operatorname{type}(\mathrm{a}))$;
- for a node $\left.\left.(\mathrm{a}, i) \in \mathscr{N}_{G_{1}}, h(\mathrm{a}, i)=g(f(\mathrm{a})), i\right)\right)$ and therefore $h(\mathrm{a}, i)=(g(f(\mathrm{a})), i)=(h(\mathrm{a}), i) ; h$ trivially preserves the free node;
- for an edge $\left(n_{1}, n_{2}\right) \in \mathscr{E}_{G_{1}}, h\left(n_{1}, n_{2}\right)=\left(g\left(f\left(n_{1}\right), g\left(f\left(n_{2}\right)\right)\right.\right.$, hence $h$ preserves edges.

If $f$ and $g$ are injective, then so is $h$. The axioms of associativity and identity law easily hold.

## A. 3 Examples of Section 2.3

Example 8 (Of no pushout in site-graphs). In the figure below, the pushout of the span below is not a site-graph: there is a conflict on site 2 of agent $B$.

Example 9 (Rules). The good rule at the right binds agents A and B to one another. Note that we do not need to specify all sites of the agents $A$ and $B$. The sites that are specified are preconditions for the application of the rule, that is the rule only applies on agents A with the sites 2 and 3 free and on agents B with site 2 free.
 ree.

Note that is site 2 of agent $A$ is mentioned on the left hand side, it also needs to appear in the right hand side. This is expressed in condition of the Definition 4. So, for example the bad rule on the right does not satisfy this condition.

## A. 4 Proofs and examples of Section 2.2

In Ref. [?] there are two conditions that need to hold for the dpo rewriting of Definition5. One of the two condition is the dangling condition defined below. The second one (called the identification condition) always holds in our setting because we only consider monos in the dpo rewriting.
Property 1 (Dangling conditions). Let $\vec{r}=L \stackrel{p}{\leftarrow} K \xrightarrow{q} R$ be a rule and let $L \xrightarrow{m} M$ be a matching in a graph M. Define the gluing points and dangling points as subsets of the nodes in $\mathscr{N}_{L}$, as follows:

$$
\begin{aligned}
& G P=p\left(\mathscr{N}_{K}\right) \\
& D P=\left\{n \in \mathscr{N}_{L}: \exists l \in \mathscr{E}_{M} \backslash m\left(\mathscr{E}_{L}\right)\right. \text { s.t. } \\
& \quad l=\left(m(n),,_{-} \text {or } l=(-, m(n))\right\} .
\end{aligned}
$$

Then we say that the dangling condition holds if $D P \subseteq G P$.
In this work, we only consider rule applications for which the dangling conditions hold. In the following lemma we show that there exists a unique $D$ such that $L \rightarrow M \leftarrow D$ is the pushout of the span $L \leftarrow K \rightarrow D$. Note that the condition on rules (of Definition 4 ) is needed for the following result.
Lemma 3. Let $L \stackrel{L}{\leftarrow} K \xrightarrow{r} R$ be a rule and let $M$ be a site-graph and let $m: L \rightarrow M$ be a matching. The DPO rewriting can be applied whenever the dangling conditions hold.

## Proof.

We first define a pushout in a "constructive" manner. Then we construct the graph $D$ and show that $M$ is the pushout of the span $\langle k, l\rangle$. Lastly, we construct $N$ and show that it is the pushout of the span $\langle k, r\rangle$.

equivalence relation with $(k(n), r(n)) \in \equiv$, for a graph $N$ to be the following graph:

- $\mathscr{N}_{N}=\left.\left(\mathscr{N}_{D} \cup \mathscr{N}_{R}\right)\right|_{\equiv}$

1. Let $R \stackrel{r}{\leftarrow} K \xrightarrow{k} D$ be a span. We define $\equiv \subseteq \mathscr{N}_{R} \times \mathscr{N}_{D}$ to be the smallest

- $\mathscr{A}_{N}=\left\{\mathrm{a}: \mathrm{a} \in n, n \in \mathscr{N}_{N}\right\}$
- $\mathscr{E}_{N}=\left\{\left(n_{1}, n_{2}\right): n_{1}, n_{2} \in \mathscr{N}_{N}\right.$
if $n_{1}, n_{2} \in$ image $(r)$ then $\left[r^{-}\left(n_{1}\right), r^{-}\left(n_{2}\right)\right.$ if $n_{1}, n_{2} \in \operatorname{image}(k)$ then $\left[k^{-}\left(n_{1}\right), k^{-}\left(n_{2}\right)\right.$

The pushout in the category of site-graphs does not always exists. When the pushout does not exists, then the graph $N$ is not a site-graph, i.e. there is a conflict in $\mathscr{E}_{N}$. We show that if $N$ is a sitegraph then it is the pushout. For that, we have to show that the graph $N$ has the universal property: for any site-graph $N^{\prime}$ and two morphisms $g^{\prime}: D \rightarrow N^{\prime}$ and $u^{\prime}: R \rightarrow N^{\prime}$ such that the diagram above commutes, there exists a unique morphism $h: N \rightarrow N^{\prime}$ such that the diagram above commutes. Let the morphism $h: N \rightarrow N^{\prime}$ be as follows:

$$
\begin{array}{rr}
h(\mathrm{a})= & u^{\prime}\left(u^{-}(\mathrm{a})\right)=g^{\prime}\left(g^{-}(\mathrm{a})\right) \\
& u^{\prime}\left(u^{-}(\mathrm{a})\right) \\
& g^{\prime}\left(g^{-}(\mathrm{a})\right) \\
h\left(n_{1}, n_{2}\right)= & u^{\prime}\left(u^{-}\left(n_{1}, n_{2}\right)\right)= \\
& \text { if } \mathrm{if} \in \operatorname{image}(u) \cap \operatorname{image}(g) \\
g^{\prime}\left(g^{-}\left(n_{1}, n_{2}\right)\right) & \\
& u^{\prime}\left(u^{-}\left(n_{1}, n_{2}\right)\right) \\
g^{\prime}\left(g^{-}\left(n_{1}, n_{2}\right)\right) & \text { if }\left(n_{1}, n_{2}\right) \in \operatorname{image}(u) \cap \operatorname{image}(g)
\end{array}
$$

The morphism preserves agent types which follows from the composition of morphisms and from the fact the diagram commutes for the morphisms $u^{\prime}$ and $g^{\prime}$. For a node $(\mathrm{a}, i) \in \mathscr{N}_{N}$, suppose that $(\mathrm{a}, i) \in \operatorname{image}(u) \cap \operatorname{image}(g)$. It follows that $\left(u^{\prime}\left(u^{-}(\mathrm{a})\right), i\right)=\left(g^{\prime}\left(g^{-}(\mathrm{a})\right), i\right) \in \mathscr{N}_{N}^{\prime}$. Therefore $h$ also preserves nodes.
The morphism $h$ is also unique. It follows from the fact that any agent or edge in $N$ is also either in graph $R$ or in graph $D$. Therefore for the diagram to commute, there is only one possible mapping for any agent or edge from $R$ (or $D$ ) into $N^{\prime}$.
2. The graph $D$ is defined as a subgraph of $M$ as follows:

- $\mathscr{N}_{D}=\mathscr{N}_{M} \backslash m\left(\mathscr{N}_{L}\right) \cup m\left(l\left(\mathscr{N}_{K}\right)\right)$
- $\mathscr{E}_{D}=\mathscr{E}_{M} \backslash m\left(\mathscr{E}_{L}\right) \cup m\left(l\left(\mathscr{E}_{K}\right)\right)$
- $\mathscr{A}_{D}=\left\{\mathrm{a}: \mathrm{a} \in n, n \in \mathscr{N}_{D}\right\}$

It is a site-graph, as it is a subgraph of $M$. The morphism $f: D \rightarrow M$ is defined as the inclusion morphism. The morphism $k: K \rightarrow D$ is defined as $k=\operatorname{lm}$ restricted to the subgraph $D$ of $M$.

Let us now show that the cospan $\langle f, m\rangle$ is the pushout of the span $\langle l, k\rangle$. For that, we show that $M$ can be obtained as in the first item of the proof from the graphs $D$ and $L$.
By manipulating the definition of the set $\mathscr{N}_{D}$ we obtain

$$
\mathscr{N}_{D} \backslash m\left(l\left(\mathscr{N}_{K}\right)\right) \cup m\left(\mathscr{N}_{L}\right)=\mathscr{N}_{M}
$$

which is equivalent to first merging sets $\mathscr{N}_{D}$ and $m\left(\mathscr{N}_{L}\right)$ and then define an equivalence class on nodes such that $(m(l(n)), k(n)) \in \equiv$, for all $n \in \mathscr{N}_{K}$. Therefore $\mathscr{N}_{M}=\left.\left(\mathscr{N}_{D} \cup m\left(\mathscr{N}_{L}\right)\right)\right|_{\equiv}$. We can make a similar argument to show that the edges of $M$ can be obtained as in the construction above, from the edges of graphs $L$ and $D$.
3. Let $N$ be the graph constructed in the first item of this proof. Suffices then to show that $N$ is a site-graph, i.e. we have to show that $\mathscr{E}_{N}$ is conflict free. Suppose by contradiction that there exists $((\mathrm{a}, i),(\mathrm{b}, j)) \in \mathscr{E}_{D}$ and $((\mathrm{a}, i),(\mathrm{c}, j)) \in \mathscr{E}_{R}$ such that $(\mathrm{a}, i) \in \mathscr{N}_{K}$. We have then that both $((\mathrm{a}, i),(\mathrm{b}, j))$ and $((\mathrm{a}, i),(\mathrm{c}, j))$ are edges in $N$, which are conflicting.
From the Definition 4 of a rule, there exists $n \in \mathscr{N}_{L}$ such that $((\mathrm{a}, i), n) \in \mathscr{E}_{L}$. As $m: L \rightarrow M$ is a mono, $((m(\mathrm{a}), i), m(n)) \in \mathscr{E}_{M}$. From the construction of $D$ above it follows that there is no $n^{\prime} \in \mathscr{N}_{D}$ such that $\left((\mathrm{a}, i), n^{\prime}\right) \in \mathscr{E}_{D}$. Contradiction.

## A.5 Proofs and examples of Section 2.3

Example 10 (Multisum). For two site-graphs $G_{1}$ and $G_{2}$, the site-graphs obtained from the multisum are the top four site-graphs in the diagram below.

In each of the graph of the multisum, the overlapping of $G_{1}$ and $G_{2}$ is highlighted by a square, i.e. the two graphs overlap on agents $A, B$, on either $A$ or $B$ or do not overlap.

Example 11 (Negative influence between rules). In the figure below, we have two rules $r_{\mathrm{A} . \mathrm{B}}, r_{\mathrm{ABC}}$ written as spans. The rule $r_{\text {A.B }}$ has a negative influence on rule $r_{\text {ABC }}$ as it unbinds agent A from agent B. Formally, this is expressed by the span $\left\langle g_{1}, g_{2}\right\rangle$ obtained by pullback from $\left\langle f_{1}, f_{2}\right\rangle \in \operatorname{multisum}\left(L_{1}, L_{2}\right)$.

Lemma 4. The pullback always exists in $\mathscr{G}$.
Proof.

Let $G_{1}, G_{2}, M$ be two site-graphs and $\vec{f}$ be a cospan as shown on the right. We define a site-graph $O$ as a subgraph of $M$ (and is therefore a site-graph), which projects into $G_{1}$ and $G_{2}$. The span $\vec{g}$ is given by a restriction on the inverse of $\vec{f}$. Lastly we show the universal property.

Let $\mathscr{A}_{O}=f_{1}\left(\mathscr{A}_{1}\right) \cap f_{2}\left(\mathscr{A}_{2}\right) \subseteq \mathscr{A}_{M}$ be a set of agents. We have that the maps $g_{1}=f_{1}^{-}\left(\mathscr{A}_{O}\right)$ and $g_{2}=f_{2}^{-}\left(\mathscr{A}_{O}\right)$ are well defined functions on the agents $\mathscr{A}_{O}$. Let $\mathscr{N}_{O}=\left\{(a, i):(a, i) \in \mathscr{N}_{M}, a \in \mathscr{A}_{0}\right\} \cup$ $\{$ free $\} \subseteq \mathscr{N}_{M}$ be a set of nodes. Finally, let $\mathscr{E}_{O}=\left\{\left(n_{1}, n_{2}\right):\left(n_{1}, n_{2}\right) \in \mathscr{E}_{M}, n_{1}, n_{2} \in \mathscr{N}_{O}\right\}$ be a set of edges which is by construction symmetric and conflict free. Then $O=\left(\mathscr{A}_{O}, \mathscr{N}_{O}, \mathscr{E}_{O}\right)$ is a site-graph, included in $M$. The maps $g_{1}, g_{2}$ are defined on nodes and edges as expected and are morphisms in $\mathscr{G}$ by construction.

Let $\mathscr{A}^{\prime}$ be the set of agents of a site-graph $O^{\prime}$ and let $\overrightarrow{g^{\prime}}$ be a span such that the diagram above commutes. Then define $h: O^{\prime} \rightarrow O$ a map such that $h\left(a^{\prime}\right)=a \Longleftrightarrow f_{1}\left(g_{1}^{\prime}\left(a^{\prime}\right)\right)=a$, for $a^{\prime} \in \mathscr{A}^{\prime}$. The map extends to nodes and edges of $O^{\prime}$. Moreover, $h$ is the unique morphism that commutes, which follows by contradiction.

Lemma 5. Let $G_{1} \leftarrow O \rightarrow G_{2}$ be the pullback of the cospan $G_{1} \rightarrow M \leftarrow G_{2} \in \operatorname{multisum}\left(G_{1}, G_{2}\right)$. Then, $G_{1} \rightarrow M \leftarrow G_{2}$ is the pushout of $G_{1} \leftarrow O \rightarrow G_{2}$.

Proof. First, we have to show that $M^{\prime}$ is a site-graph, where the span $G_{1} \leftarrow O \rightarrow G_{2}$ is the pullback of a cospan $G_{1} \rightarrow M \leftarrow G_{2}$ and $G_{1} \rightarrow M^{\prime} \leftarrow G_{2}$ is the pushout of $G_{1} \leftarrow O \rightarrow G_{2}$. If $M^{\prime}$ is obtained from the pushout, then there exists a unique mono $M^{\prime} \rightarrow M$. Therefore, from the Definition 2 of morphism, if there is a conflict in $M^{\prime}$ then there is a conflict in $M$ as well.
Secondly, let us show the hypothesis. Let us suppose by contradiction, that the cospan $G_{1} \rightarrow M \leftarrow G_{2}$ is not the pushout of the span $G_{1} \leftarrow O \rightarrow G_{2}$. We denote the pushout as the cospan $G_{1} \rightarrow P \leftarrow G_{2}$. From the definition of the pushout we have that there exists a unique morphism $m: P \rightarrow M$ for which the diagram on the right commutes.

Let us distinguish between two cases:

- $G_{1} \rightarrow P \leftarrow G_{2} \notin$ multisum $\left(G_{1}, G_{2}\right)$. If the pushout is not in the multisum, then there exists $M^{\prime} \in$ multisum $\left(G_{1}, G_{2}\right)$ such that there exists a morphism $m^{\prime}: M^{\prime} \rightarrow P$. But then there exists a morphism $m m^{\prime}: M^{\prime} \rightarrow M$. However as both $M, M^{\prime}$ are in the multisum, then $M \cong M^{\prime}$ and, hence $M \cong P$.
- $G_{1} \rightarrow P \leftarrow G_{2} \in \operatorname{multisum}\left(G_{1}, G_{2}\right)$. Then let us denote with $M^{\prime \prime}$ the pushout-object of the span $M \leftarrow O \rightarrow P$. It follows that both $M$ and $P$ embed into $M^{\prime \prime}$. From the definition of the multisum, it follows that $M \cong P$.

Let us note that the Lemma above is used in the definition of influence between rules in Ref.[?].

## A. 6 Proofs of Section 3

Lemma 6. Let $\theta$ be a trace and let $e, e^{\prime} \in E$ be two events with $\mathscr{A}_{1}(\theta)=(E, \ell, \xrightarrow{+}, \rightarrow)$. If $e \xrightarrow{+\vec{f}} e^{\prime}$ then $\ell(e) \xrightarrow{+\vec{f}} \ell\left(e^{\prime}\right)$, for some $\vec{f} \in \operatorname{span}(\mathscr{G})$ (and similarly for negative influence).

Proof. Let $\theta$ be a trace such that $\mathscr{A}_{1}(\theta)=(E, \ell, \xrightarrow{+} \xrightarrow{-})$. For the two events $e_{1}, e_{2}$ in $E$ and a cospan $f$ such that $e \xrightarrow{+\vec{f}} e^{\prime}$, there exists two transitions $t_{1}, t_{2} \in \theta$ such that $t_{1}: M_{1} \stackrel{m_{1} r_{1}}{\Rightarrow} N_{1}$ and $t_{2}: M_{2} \stackrel{m_{2}, r_{2}}{\Rightarrow} N_{2}$, for some graphs $M_{i}, N_{i}$, morphisms $m_{i}$ and the underlying rules $\vec{r}_{i}=L_{i} \leftarrow K_{i} \rightarrow R_{i}, i \in\{1,2\}$. Moreover, from the Definition 12 it follows that $\left(t_{1}, t_{2}, \vec{f}\right) \in<_{\theta}$ and $\ell\left(e_{i}\right)=r_{i}, i \in\{1,2\}$. From the Definition 11 it follows that $r_{1} \xrightarrow{+\vec{f}} r_{2}$.

Proof of Lemma $T$ Let $\theta$ be a trace, let $\mathscr{A}_{1}(\theta)=(E, \ell \xrightarrow{+}, \xrightarrow{-})$ be the intermediate structure and $\mathscr{A}_{2}(E, \ell, \xrightarrow{+}$ $\xrightarrow{-} \rightarrow)=(E, \ell, \leq, \vdash)$ be a poset. Let $e, e^{\prime} \in E$ be two events such that $e<e^{\prime}$. Then from the Definition 13 , it follows $e \xrightarrow{+\vec{f}} e^{\prime}$, for some span $\vec{f}$. From Lemma 6, then we have that $\ell(e) \xrightarrow{+\vec{f}} \ell\left(e^{\prime}\right)$.

The proof is similar for the non causal precedence.
Schematically, the abstractions and concretisations of Definitions 12,131416 are represented as follows:

Example 12 (The two-steps abstraction: Example 3 revisited). Let us consider the trace $\theta=t_{1} ; t_{2} ; t_{3} ; t_{4}$ of example 2. The first abstraction constructs the structure $(E, \ell \xrightarrow{\rightarrow}, \vec{\rightarrow})$. Let $\vec{f}, \vec{g}, \vec{h}, \vec{i}, \vec{j} \in \operatorname{span}(\mathscr{G})$ be the spans shown in the figure below:

Then the relations $\xrightarrow{+}, \xrightarrow{-}$ are defined as follows:

$$
e_{1} \xrightarrow{+\vec{f}} e_{2} \quad e_{1} \xrightarrow{+\vec{g}} e_{3} \quad e_{2} \xrightarrow{+\vec{h}} e_{4} \quad e_{3} \xrightarrow{+\vec{i}} e_{4} \quad e_{3} \xrightarrow{-\vec{j}} e_{2} .
$$

The second abstraction removes the spans in the relations $\xrightarrow{+}, \xrightarrow{-}$. At the end we obtain the structure $(E, \ell,<, \Vdash)$ with $<=\left\{\left(e_{1}, e_{2}\right) ;\left(e_{1}, e_{3}\right) ;\left(e_{2}, e_{4}\right) ;\left(e_{3}, e_{4}\right)\right\}$ and $\Vdash=\left\{\left(e_{2} ; e_{3}\right)\right\}$.
Example 13 (The two-steps concretisation: Example 4 revisited). Consider a poset of events $e_{1}, e_{2}$ and $e_{3}$ with labels $\overrightarrow{r_{1}}, \overrightarrow{r_{2}}$ and $\overrightarrow{r_{3}}$, as in Example 4. The first concretisation step, as we have argued, retrieves the structure $(E, \ell, \xrightarrow{+}, \stackrel{-}{\longrightarrow})$ with the relation $\xrightarrow{+}$ defined as follows:

$$
e_{1} \xrightarrow{+\vec{f}} e_{2} \quad e_{2} \xrightarrow{+\vec{h}} e_{3}
$$

and $\xrightarrow{-}=\emptyset$.
The second concretisation step needs a function concrete. For our example the following works:

Providing an implementation for the function $f$ is outside the scope of this paper and we leave it as future work. For the case of Kappa, an implementation is available at https://github.com/ Kappa-Dev/PosetLogic.
Example 14 (More coarse-grained abstractions). Recall that for the trace $\theta$ of example 2 our abstraction constructs the poset $s$ of the example 3. Note that there are other abstractions possible from a causal trace. For example, one can also forget the prevention relations between events and retrieve "regular" posets, i.e. sets of events equipped with only one partial order, the precedence relation.

In Example 2 if we forget prevention on trace $\theta$, we obtain the same set of events $\left\{e_{1}, e_{2}, e_{3}, e_{4}\right\}$ ) but equipped with only the precedence relation $<=\left\{\left(e_{1}, e_{2}\right) ;\left(e_{1}, e_{3}\right) ;\left(e_{2}, e_{4}\right) ;\left(e_{3}, e_{4}\right)\right\}$. From this poset we can concretise a trace in which event $e_{3}$ occurs before event $e_{2}$, which is not possible in our concretisation.

Another possible abstraction consists of remembering the direct precedence instead of the indirect one. In this case we do not detect that event $e_{2}$ is a precedent for event $e_{4}$.

None of these abstractions are "wrong" in any sense, but do not keep as much information about the original trace as the abstraction we defined. Our choice is motivated by the application to Kappa, where the indirect enablement and prevention are deemed important.

Proof of theorem 1 Suffices to show that for any trace $\theta$ there exists a concretisation function for the poset $\mathscr{A}_{2} \mathscr{A}_{1}(\theta)$ such that the constraints in Definitions 1614 hold. It follows from the Definitions 1213 of abstractions.

Consider now a trace $\theta^{\prime} \in \mathscr{C} \mathscr{A}_{2} \mathscr{A}_{1}(\theta)$. Both traces $\theta$ and $\theta^{\prime}$ meet the constraints in Definitions 1614 It follows that $\mathscr{A}_{2} \mathscr{A}_{1}(\theta) \cong \mathscr{A}_{2} \mathscr{A}_{1}\left(\theta^{\prime}\right)$ using the Definitions 12|13.

## A. 7 Independence, enablement and prevention in graph rewriting

In this section we revisit the graph rewriting theory from Ref. [?] adapted to site-graphs.
The next Lemma asserts that when $t_{1} \diamond_{\text {par }} t_{2}$, we can construct a $t_{1}^{\prime}$ and $t_{2}^{\prime}$ to sequentialize either way, $t_{1} ; t_{2}^{\prime}$ or $t_{2} ; t_{1}^{\prime}$, with the same net effect. Likewise, when $t_{1} \diamond_{\text {seq }} t_{2}$, we can find a $t_{1}^{\prime}$ and $t_{2}^{\prime}$ to swap the order from $t_{1} ; t_{2}$ into $t_{2}^{\prime} ; t_{1}^{\prime}$ with, again, the same net effect. The Lemma is a variant of a result from Ref. [?] adapted to site-graphs.

Lemma 7 (Permutation of independent transitions). Consider two transitions $t_{1}: M \stackrel{m_{1} r_{1}}{\Rightarrow} M_{1}$ and $t_{2}$ : $M^{m_{2}, r_{2}} \Rightarrow M_{2}$. If $t_{1} \diamond_{\text {par } t_{2}}$ then there exists an $M^{\prime} \in Q$ and two transitions $t_{2}^{\prime}: M_{1} \stackrel{m_{2}^{\prime}, r_{2}}{\Rightarrow} M^{\prime}$ and $t_{1}^{\prime}: M_{2} \stackrel{m_{l}^{\prime}, r_{1}}{\Rightarrow} M^{\prime}$ for some matchings $m_{2}^{\prime}, m_{1}^{\prime} \in \operatorname{hom}(\mathscr{G})$. Moreover, $t_{1} \diamond_{\text {seq }} t_{2}^{\prime}\left(\operatorname{and} t_{2} \diamond_{\text {seq }} t_{1}^{\prime}\right)$.

Consider two transitions $t_{1}: M \stackrel{m_{1}}{\Rightarrow} r_{1} M_{1}$ and $t_{2}: M_{1} \stackrel{m_{2}}{\Rightarrow} r_{2} M_{2}$. If $t_{1} \diamond_{\text {seq }} t_{2}$ then there exists an $M^{\prime} \in Q$ and two transitions $t_{2}^{\prime}: M \stackrel{m_{2}^{\prime}, r_{2}}{\Rightarrow} M^{\prime}$ and $t_{1}^{\prime}: M^{\prime} \stackrel{m_{1}^{\prime}, r_{1}}{\Rightarrow} M_{2}$ for some matchings $m_{2}^{\prime}, m_{1}^{\prime} \in \operatorname{hom}(\mathscr{G})$. Moreover, $t_{1} \diamond_{\text {par }} t_{2}^{\prime}$.

Proof. From the Definition 10 of parallel independence we have that if $t_{1} \diamond_{\text {par }} t_{2}$ then there exists two transitions $t_{2}^{\prime}: M_{1} \stackrel{m_{2}^{\prime} r_{2}}{\Rightarrow} M_{1}^{\prime}$ and $t_{1}^{\prime}: M_{2} \stackrel{m_{1}^{\prime}, r_{1}}{\Rightarrow} M_{2}^{\prime}$ for some matchings $m_{2}^{\prime}, m_{1}^{\prime} \in \operatorname{hom}(\mathscr{G})$. We have to show that $M_{1}^{\prime} \cong M_{2}^{\prime}$. For this we show that the parts of $M$ modified by $r_{1}$ and the parts modified by $r_{2}$ are disjoint and therefore the order in which they occur does not matter.

We fix some notations. We write $n_{1}: R_{1} \rightarrow M_{1}, n_{2}: R_{2} \rightarrow M_{2}, n_{1}^{\prime}: R_{1} \rightarrow M_{2}^{\prime}$ and $n_{2}^{\prime}: R_{1} \rightarrow M_{1}^{\prime}$. Let us also denote $\mathscr{A}_{1}^{\prime} \subseteq \mathscr{A}_{M}$ the set of agents deleted by the application of $r_{1}$ and $\mathscr{A}_{1}^{\prime \prime} \subseteq \mathscr{A}_{M_{1}}$ the set of agents created by $r_{1}$. We use similar notations for $\mathscr{A}_{2}^{\prime} \subseteq \mathscr{A}_{M}, \mathscr{A}_{2}^{\prime \prime} \subseteq \mathscr{A}_{M_{2}}$.

Then we have that

$$
\mathscr{A}_{M_{1}}=\mathscr{A}_{M} \backslash \mathscr{A}_{1}^{\prime} \cup \mathscr{A}_{1}^{\prime \prime}
$$

and similarly for $M_{2}$ :

$$
\mathscr{A}_{M_{2}}=\mathscr{A}_{M} \backslash \mathscr{A}_{2}^{\prime} \cup \mathscr{A}_{2}^{\prime \prime}
$$

The sets $\mathscr{A}_{1}^{\prime}$ and $\mathscr{A}_{2}^{\prime}$ are disjoint, as the transitions are independent. It implies that $m_{2}^{\prime}\left(m_{2}^{-}\left(\mathscr{A}_{2}^{\prime}\right)\right) \in \mathscr{A}_{M_{1}}$ and similarly for $n_{2}^{\prime}\left(n_{2}^{-}\left(\mathscr{A}_{2}^{\prime \prime}\right)\right) \in \mathscr{A}_{M_{1}^{\prime}}$ the agents created by $r_{2}$. Therefore

$$
\begin{aligned}
\mathscr{A}_{M_{1}^{\prime}} & =\mathscr{A}_{M_{1}} \backslash m_{2}^{\prime}\left(m_{2}^{-}\left(\mathscr{A}_{2}^{\prime}\right)\right) \cup n_{2}^{\prime}\left(n_{2}^{-}\left(\mathscr{A}_{2}^{\prime \prime}\right)\right) \\
& =\mathscr{A}_{M} \backslash\left(\mathscr{A}_{1}^{\prime} \cup m_{2}^{\prime}\left(m_{2}^{-}\left(\mathscr{A}_{2}^{\prime}\right)\right)\right) \cup\left(\mathscr{A}_{1}^{\prime \prime} \cup n_{2}^{\prime}\left(n_{2}^{-}\left(\mathscr{A}_{2}^{\prime \prime}\right)\right)\right) .
\end{aligned}
$$

and similarly,

$$
\begin{aligned}
\mathscr{A}_{M_{2}^{\prime}} & =\mathscr{A}_{M_{2}} \backslash m_{1}^{\prime}\left(m_{1}^{-}\left(\mathscr{A}_{1}^{\prime}\right)\right) \cup n_{1}^{\prime}\left(n_{1}^{-}\left(\mathscr{A}_{2}^{\prime \prime}\right)\right) \\
& =\mathscr{A}_{M} \backslash\left(\mathscr{A}_{2}^{\prime} \cup m_{1}^{\prime}\left(m_{1}^{-}\left(\mathscr{A}_{1}^{\prime}\right)\right)\right) \cup\left(\mathscr{A}_{2}^{\prime \prime} \cup n_{1}^{\prime}\left(n_{1}^{-}\left(\mathscr{A}_{1}^{\prime \prime}\right)\right)\right) .
\end{aligned}
$$

From the Definition 10 of parallel independence we have that there exists the bijections

$$
\begin{aligned}
& f_{1}: \mathscr{A}_{1}^{\prime} \rightarrow m_{1}^{\prime}\left(m_{1}^{-}\left(\mathscr{A}_{1}^{\prime}\right)\right) ; f_{2}: \mathscr{A}_{2}^{\prime} \rightarrow m_{2}^{\prime}\left(m_{2}^{-}\left(\mathscr{A}_{2}^{\prime}\right)\right) ; \\
& g_{1}: \mathscr{A}_{1}^{\prime \prime} \rightarrow n_{1}^{\prime}\left(n_{1}^{-}\left(\mathscr{A}_{1}^{\prime \prime}\right)\right) ; g_{2}: \mathscr{A}_{2}^{\prime \prime} \rightarrow n_{2}^{\prime}\left(n_{2}^{-}\left(\mathscr{A}_{2}^{\prime \prime}\right)\right) .
\end{aligned}
$$

Therefore the we can define a bijection $h: \mathscr{A}_{M_{1}^{\prime}} \rightarrow \mathscr{A}_{M_{2}^{\prime}}$ between the agents of $M_{1}^{\prime}$ and the agents of $M_{2}^{\prime}$ as follows

$$
h=\operatorname{id} \backslash\left(f_{1} \cup f_{2}\right) \cup\left(g_{1} \cup g_{2}\right),
$$

where id is the identity function on the agents of $M$. As it is obtained from operations on morphisms, the bijection $h$ preserves agent types and nodes. Similarly we proceed to construct the bijection between the egdes of $M_{1}^{\prime}$ and $M_{2}^{\prime}$. We obtain a isomorphism between the site-graph $M_{1}^{\prime}$ and $M_{2}^{\prime}$.

In a similar fashion we can prove the second part of this lemma.

Example 15 (Parallel and sequential independence). In the figure on the right we have two sequential transitions that we denote with $t_{1}$ : $M_{1} \stackrel{m_{1}, r_{\mathrm{AB}}}{\Rightarrow} M_{2}$ and $t_{2}: M_{2} \stackrel{m_{2}, r_{\mathrm{AC}}}{\Rightarrow} M_{3}$. The two transitions are sequential independent: there exists $m_{2}^{\prime}$ a morphism from the left hand side of $r_{\mathrm{AC}}$ to $M_{1}$ such that $m_{2}^{\prime} \operatorname{mix}\left(t_{1}\right)=m_{2}$. Thanks to Lemma 7 we can also rewrite transition $t_{2}$ into a transition $t_{2}^{\prime}: M_{1} \stackrel{m_{2}^{\prime}, r_{\mathrm{AC}}}{\Rightarrow} M_{2}^{\prime}$ as shown in the figure below. Transitions $t_{1}$ and $t_{2}^{\prime}$ become then parallel independent. Lastly, note that in the figure, we can also rewrite $t_{1}$ into $t_{1}^{\prime}: M_{2}^{\prime} \stackrel{\prime}{\prime} \stackrel{r_{1}^{\prime}, r_{\mathrm{AB}}}{\Rightarrow} M_{3}$, with $t_{2}^{\prime}$ and $t_{1}^{\prime}$ sequential independent.

Let us now revisit the Definition 11 of enablement and prevention.

direct enablement

indirect enablement

Definition 19 (Direct and indirect enablement). Let $t_{1}: M_{1} \stackrel{m_{1}, r_{1}}{\Rightarrow} N_{1}$ and $t_{2}: M_{2} \stackrel{m_{2}, r_{2}}{\Rightarrow} N_{2}$ be two transitions bracketing a trace $\theta: t_{1} ; t_{1}^{\prime} ; t_{2}^{\prime} ; \cdots t_{n}^{\prime} ; t_{2}$. The rules inducing $t_{i}, i \in\{1,2\}$, are $\vec{r}_{i}=L_{i} \leftarrow K_{i} \rightarrow R_{i}$ with matchings $m_{i} \in \operatorname{hom}(\mathscr{G})$ into $M_{1}$ and $M_{2}$, respectively. The span $N_{1} \leftarrow D \rightarrow M_{2}$ is the composition of $\operatorname{mix}\left(t_{1}^{\prime}\right) \circ \cdots \circ \operatorname{mix}\left(t_{n}^{\prime}\right)$.
direct enablement Let $\vec{g}$ be a span such that $\overrightarrow{r_{1}} \xrightarrow{+\vec{g}} \overrightarrow{r_{2}}$ and such that $\vec{g}$ is the pullback of $\vec{f} \in$ multisum $\left(R_{1}, L_{2}\right)$.
If there exists a span $\vec{h}$ such that the diagram below on the left commutes then $t_{1}$ directly enables $t_{2}$, denoted $t_{1} \prec t_{2}$.
indirect enablement Let $\vec{g}$ be a span such that $\overrightarrow{r_{1}} \xrightarrow{+\vec{g}} \overrightarrow{r_{2}}$. If the diagram below on the right commutes then $t_{1}$ indirectly enables $t_{2}$, denoted $t_{1}<t_{2}$.
The notion of direct enablement is useful in the characterization of non-independent transitions (see Lemmas (8, 10). However, as we suggested in the example 2, indirect enablement captures more dependencies between transitions.

Example 16 (Example 2 revisited). Transition $t_{1}$ is a direct enabler of $t_{2}$ and $t_{3}$. Transition $t_{2}$ is an indirect enabler for $t_{4}$.
Definition 20 (Direct and indirect prevention). Consider two transitions $t_{1}: M_{1} \stackrel{m_{1}, r_{1}}{\Rightarrow} N_{1}$ and $t_{2}: M_{2} \stackrel{m_{2}, r_{2}}{\Rightarrow} N_{2}$ in a trace $\theta: t_{1} ; t_{1}^{\prime}: t_{2}^{\prime} ; \cdots t_{n}^{\prime} ; t_{2}$. The rules inducing $t_{i}, i \in\{1,2\}$, are $\overrightarrow{r_{i}}=L_{i} \leftarrow K_{i} \rightarrow R_{i}$ with matchings $m_{i} \in \operatorname{hom}(\mathscr{G})$ into $M_{1}$ and $M_{2}$, respectively. The span $M_{1} \leftarrow D \rightarrow M_{2}$ is the composition of $\operatorname{mix}\left(t_{1}\right) \circ$ $\operatorname{mix}\left(t_{1}^{\prime}\right) \circ \cdots \circ \operatorname{mix}\left(t_{n}^{\prime}\right)$.
direct prevention Let $\vec{g}$ be a span such that $\overrightarrow{r_{2}} \xrightarrow{-\vec{g}} \overrightarrow{r_{1}}$ and such that $\vec{g}$ is the pullback of $\vec{f} \in$ multisum $\left(L_{1}, L_{2}\right)$. If there exists a span $\vec{h}$ such that the diagram below on the left commutes then $t_{2}$ directly prevents $t_{1}$, denoted $t_{2}=t_{1}$.
indirect prevention Let $\vec{g}$ be a span such that $\overrightarrow{r_{2}} \xrightarrow{-\vec{g}} \overrightarrow{r_{1}}$. If the diagram below on the right commutes then $t_{2}$ indirectly prevents $t_{1}$, denoted $t_{2} \dashv t_{1}$.

direct prevention

indirect prevention

Note that $t_{1} \prec t_{2} \Longrightarrow t_{1}<t_{2}$ and $t_{1} \exists t_{2} \Longrightarrow t_{1} \dashv t_{2}$, but not the reverse.
We next relate enablement and prevention to non-independence. First we show that when restricting our definitions to the case of consecutive transitions, enablement and prevention are included in the negation of sequential and parallel independence.
Lemma 8. Consider two sequential transitions $t_{1}: M \stackrel{m_{1}, r_{1}}{\Rightarrow} M_{1}$ and $t_{2}: M_{1} \stackrel{m_{2}, r_{2}}{\Rightarrow} M_{2}$ and let $g_{1}$ be the morphism $D_{1} \rightarrow M_{1}$, where $D_{1}$ is the context graph of $t_{1}$. Transition $t_{1}$ direct enables transition $t_{2}$ iff there exists no morphism $j: L_{2} \rightarrow D_{1}$ such that $g_{1} j=m_{2}$.
Lemma 9. Consider two parallel transitions $t_{1}: M \stackrel{m_{1} r_{1}}{\Rightarrow} M_{1}$ and $t_{2}: M \stackrel{m_{2}, r_{2}}{\Rightarrow} M_{2}$ and let $f_{1}$ be the morphism $D_{1} \rightarrow M$, where $D_{1}$ is the context graph of $t_{1}$. Transition $t_{1}$ is directly prevents transition $t_{2}$ iff there is no morphism $j: L_{2} \rightarrow D_{1}$ such that $f_{1} j=m_{2}$.

Lastly, the following two Lemmas assert that two non-independent transitions are either in an enabling relation or they can be rewritten as preventing transitions.
Lemma 10. Consider two sequential transitions $t_{1}: M \stackrel{m_{1} r_{1}}{\Rightarrow} M_{1}$ and $t_{2}: M_{1} \stackrel{m_{2} r_{2}}{\Rightarrow} M_{2}$. Let $f_{1}$ and $g_{1}$ be the morphisms $D_{1} \rightarrow M$ and $D_{1} \rightarrow M_{1}$, respectively, where $D_{1}$ is the context graph of $t_{1}$. If the sequential transitions $t_{1}$ and $t_{2}$ are not independent, then either (i) $t_{1}<t_{2}$ or (ii) there exists a morphism $j: L_{2} \rightarrow M$ such that $g_{1} j=m_{2}$; and there exists a graph $M_{2}^{\prime}$ and a transition $t_{2}^{\prime}: M \stackrel{f_{1} j r_{2}}{\Rightarrow} M_{2}^{\prime}$ with $t_{2}^{\prime} \neq t_{1}$.
Lemma 11. If two parallel transitions $t_{1}$ and $t_{2}$ are not parallel independent then either $t_{1} \neq t_{2}$ or $t_{2} \neq t_{1}$ (or both).

## A.7.1 Proofs of Appendix subsection A. 7

Proof of Lemma 8
Let us first make an observation. For the two rules $r_{1}$ and $r_{2}$, where we have the morphisms $R_{1} \rightarrow M_{1}$ and $L_{2} \rightarrow M_{1}$, there exists a unique $R_{1} \rightarrow M \leftarrow L_{2} \in$ multisum $\left(R_{1}, L_{2}\right)$ that make the diagram on the right commutes (from Definition 6). The pullback of $R_{1} \rightarrow M_{1} \leftarrow L_{2}$ is the same as the pullback of $R_{1} \rightarrow M \leftarrow L_{2}$, which follows from Lemma 5 .

We depict the two transitions in the figure below. Let $R_{1} \leftarrow O \rightarrow L_{2}$ be the pullback of the cospan $R_{1} \rightarrow M_{1} \leftarrow L_{2}$ and let $K_{1} \leftarrow P \rightarrow O$ be the pullback of $K_{1} \rightarrow R_{1} \leftarrow O$. We proceed by showing that in the diagram below

the mono $p: P \rightarrow O$ is an iso iff there exists a morphism $j: L_{2} \rightarrow D_{1}$ such that $g_{1} j=m_{2}$. Let us denote $o: O \rightarrow L_{2}$ the morphism between $O$ and $L_{2}$ and $o^{\prime}: O \rightarrow R_{1}$ be the morphism between $O$ and $R_{1}$.

- Suppose that $p: P \rightarrow O$ is an iso. We denote $p^{\prime}: O \rightarrow K_{1}$ the composition of $p$ and $P \rightarrow K_{1}$. We define $j: L_{2} \rightarrow D_{1}$ as follows

$$
\begin{aligned}
j(\mathrm{a})= & k_{1}\left(p^{\prime}\left(o^{-}(\mathrm{a})\right)\right) \\
& g_{1}^{-}\left(m_{2}(\mathrm{a})\right) \\
j((\mathrm{a}, i))= & (j(\mathrm{a}), i) \\
j\left(\left[n_{1}, n_{2}\right]\right)= & {\left[j\left(n_{1}\right), j\left(n_{2}\right)\right] }
\end{aligned}
$$

$$
\begin{array}{r}
\text { for a } \in \operatorname{image}(o)\left(\mathscr{A}_{0}\right) \\
\text { for a } \in \mathscr{A}_{L_{2}} \backslash \operatorname{image}(o)\left(\mathscr{A}_{0}\right) \\
\text { for a node }(\mathrm{a}, i) \in \mathscr{N}_{L_{2}} \\
\text { for an edge }\left[n_{1}, n_{2}\right] \in \mathscr{E}_{L_{2}} .
\end{array}
$$

In what follows we show that $j$ is (i) well defined on agents; (ii) preserves nodes and edges; (iii) is a mono.
Let $o(O)=L_{2}^{\prime} \subseteq L_{2}$ be the image of $o: O \rightarrow L_{2}$. For any agent a in $L_{2}^{\prime}$, we have that $j(\mathrm{a})=$ $k_{1}\left(p^{\prime}\left(o^{-}(\mathrm{a})\right)\right)$. The function $o^{-}: L_{2}^{\prime} \rightarrow O$ is not necessarily a morphism, as it might not preserve nodes and the edges between nodes. It is however a function well defined on agents, which follows from $o$ being a mono. Moreover, for any node or edge in $L_{2}^{\prime}, o^{-}$preserves them into $O$.
Consider now $x$ an agent, a node or an edge in $L_{2}$ such that $x \notin L_{2}^{\prime}$. We have that $R_{1} \leftarrow O \rightarrow L_{2}$ is the pullback of $R_{1} \rightarrow M_{1} \leftarrow L_{2}$ and therefore, if $x \in L_{2}, x \notin \operatorname{image}(o)(O)$ then $m_{2}(x) \in M_{1}$, which we denote $x^{M}$. We also have that there exists no $x^{R} \in R_{1}, x^{R} \in \operatorname{image}\left(o^{\prime}\right)(O)$, that maps into $x^{M}$.
We have that $D_{1} \rightarrow M_{1} \leftarrow R_{1}$ is the pushout of $D_{1} \leftarrow K_{1} \rightarrow R_{1}$. For $x^{M} \in M_{1}$ and not in $R_{1}$ we have that there exists $x^{D} \in D_{1}$ such that $g_{1}\left(x^{D}\right)=x^{M}$. Therefore we can define $j(x)=g_{1}^{-}\left(m_{2}(x)\right)$, for all $x \in L_{2} \backslash \operatorname{image}(o)$. This proves (i) and (ii).
The function $j$ satisfies (iii) as any agent, node or edge in graph $L_{2}$ is either in $L_{2}^{\prime}$ or in $L_{2} \backslash L_{2}^{\prime}$.

- Let us now show that if there exists $j: L_{2} \rightarrow D_{1}$ such that $g_{1} j=m_{2}$ then the morphism $p: P \rightarrow O$ is an iso.
For any $x$ (agent, node or edge) in $O$ we have that there exists $x^{L} \in L_{2}$ such that $o\left(x^{L}\right)=x$ and similarly for $x^{R} \in R_{1}, o^{\prime}(x)=x^{R}$. As $O$ is the pullback, both $x^{L}$ and $x^{R}$ map into the same $x^{M} \in M_{1}$. Also, $m_{2}\left(x^{L}\right)=g_{1}\left(j\left(x^{L}\right)\right)$ and therefore there exists $x^{D} \in D_{1}$ such that $j\left(x^{L}\right)=x^{D}$ and $g_{1}\left(x^{D}\right)=x^{M}$. The span $D_{1} \rightarrow M_{1} \leftarrow R_{1}$ is the pushout of $D_{1} \leftarrow K_{1} \rightarrow R_{1}$ and there exists $x^{D} \in D_{1}, x^{R} \in R_{1}$ that map into $x^{M}$. It implies that there exists $x^{k} \in K_{1}$ such that $x^{k}$ maps into $x^{D}$ and $x^{R}$.
The span $K_{1} \leftarrow P \rightarrow O$ is the pullback of $K_{1} \leftarrow R_{1} \rightarrow O$ and there exists $x^{k} \in K_{1}, x^{O} \in O_{1}$ that map into $x^{R}$. Therefore there exists $x^{P} \in P$ such that $p\left(x^{P}\right)=x$ for all nodes or edges $x \in O$. It implies that $p$ is surjective.
As $p$ is both surjective and injective (by definition) we conclude that $p$ is indeed an iso.

Proof of Lemma 9 This proof is similar to the one of Lemma 8 .
Proof of Lemma 10 If $M \stackrel{m_{1}, r_{1}}{\Rightarrow} M_{1}$ and $M_{1} \stackrel{m_{2}, r_{2}}{\Rightarrow} M_{2}$ are not sequentially independent, from Definition 10 , it follows two possible cases:

- there is no morphism $j: L_{2} \rightarrow D_{1}$ such that $g_{1} j=m_{2}$. From Lemma 8, in this case $t_{1}<t_{2}$. We have proved then case (i) from the hypothesis.
- there is no morphism $i: R_{1} \rightarrow D_{2}$ such that $f_{2} i=n_{1}$, but there exists the morphism $j: L_{2} \rightarrow D_{1}$ such that $g_{1} j=m_{2}$. It implies, from Lemma 7 that there exists $M^{\prime} \in Q$ and $t_{2}^{\prime}: M \stackrel{m_{2}^{\prime}, r_{2}}{\Rightarrow} M^{\prime}$, for some morphism $m_{2}^{\prime}$ such that $t_{1}$ with is not parallel independent of $t_{2}^{\prime}$.
From the Definition 10 of parallel independence if $t_{1}$ and $t_{2}^{\prime}$ are not parallel independent it follows that there is no morphism $i^{\prime}: L_{1} \rightarrow D_{2}$ such that $f_{2} i^{\prime}=n_{1}$. Then by Lemma 9, we conclude that $t_{2}^{\prime}=t_{1}$.

Proof of Lemma 11 It follows from Definition 10 and Lemma 9 .

## A. 8 On the implementation

In the implementation we use two simpliying assumptions, that holds for stories generated by KaSim:

- Let $\theta$ be a trace. For all $M_{i}$ mixtures of $\theta$, for all agents a $\in M_{i}$, there exists a transition of $\theta$ $M_{j} \stackrel{m r}{\Rightarrow} M_{j+1}$, with $\vec{r}=L \leftarrow K \rightarrow R$, such that $\mathrm{a} \notin \mathscr{A}_{L}$ and $\mathrm{a} \in \mathscr{A}_{R}$.
- Let $\vec{r}=L \leftarrow K \rightarrow R$ be a rule. For any a $\in \mathscr{A}_{R}$, if a $\notin q\left(\mathscr{N}_{K}\right)$ then $\forall i<\operatorname{site}(\operatorname{type}(\mathrm{a})),(\mathrm{a}, i) \in \mathscr{N}_{R}$ and $\exists n \in \mathscr{N}_{R}$ such that $((\mathrm{a}, i), n) \in \mathscr{E}_{R}$.

The first condition, informally, asks that any agent used at some point in a trace has an "introductory" rule, i.e. a rule that creates the agent. The second condition requires that the agents created by a rule are fully specified, i.e. all sites are involved in an edge.

These two assumptions simplify the implementation of the concretisation function, but do not have an impact on the theoretical development presented in the main text.

A correct concretisation, as mentioned in the main text, correct concretisations are cumbersome to define. Here we give two conditions that have to hold, the rest being similar.

Definition 21 (Valid poset). A poset $s=(E, \xrightarrow{+} \xrightarrow{-}, \ell)$ is valid if it is directed w.r.t. the transitive and reflexive closure of $\xrightarrow{+}$ and if the following constraints are meet:
no influence is empty Let $e_{1}, e_{2} \in s$ be two events. If $e_{1} \xrightarrow{+\vec{f}} e_{2}$ or $e_{1} \xrightarrow{-\vec{f}} e_{2}$ then $\vec{f}$ is not empty;
constraints on the influence between rules for positive meets Let $e_{1}, e_{2}, e_{3}$ be three events in $s$ such that there exists $\vec{f}=R_{1} \leftarrow O_{1} \rightarrow L_{3}$ and $\vec{g}=R_{2} \leftarrow O_{2} \rightarrow L_{3}$ two spans with $e_{1} \xrightarrow{+\vec{f}} e_{3}$ and $e_{2} \xrightarrow{+\vec{g}} e_{3}$. Let $O_{1} \leftarrow O \rightarrow O_{2}$ be the pullback of the span $O_{1} \rightarrow L_{3} \leftarrow O_{2}$. Then one of the following holds:

- either there exists the morphisms $O \rightarrow K_{1}$ and $O \rightarrow K_{2}$ that commute in the diagram below

- or there exists the morphism $O \rightarrow K_{1}$ but no morphism $O \rightarrow K_{2}$ that commutes. Then there exists $\overrightarrow{f^{\prime}}: R_{2} \leftarrow O^{\prime} \rightarrow L_{1}$, with $O \subseteq O^{\prime}$ for which $e_{2} \xrightarrow{+\overrightarrow{f^{\prime}}} e_{1}$.

We call a resource any non empty site-graph that appears in one but not both sides of a rule, as for instance an agent or an edge. A correct concretisation is consistent w.r.t. all resources used in the concretised trace.

In the definition above a resource is modeled as a span. The first condition says that if there is a relation between two events in a poset, then necessarily they have a non-empty shared resource. The second condition checks that whenever an event $e_{3}$ shares the same resource with two other events $e_{1}$ and $e_{2}$, then the two events also share the resource.

[^0]:    ${ }^{1}$ In Ref.[?], a partially ordered set of events that account for an outcome was dubbed a "story", which is akin to the biological notion of a "pathway".

[^1]:    ${ }^{2}$ We write $f g(x)=f(g(x))$, with $x$ in the domain of $g$, for morphisms composition.

[^2]:    ${ }^{3}$ Positive and negative influence were referred to as activation, inhibition or overlaps in Refs.[?, Section 3.4],[?, Section 4.2.3][?].

[^3]:    ${ }^{4}$ For immediate transitions, enablement and prevention coincide with the sequential dependence and critical pairs, respectively, of Refs. [?, ?, ?]. See the appendix for more details.
    ${ }^{5}$ We can define a function id :T $\rightarrow \mathbb{N}$ from transitions to natural numbers such that $\operatorname{id}\left(t_{i}\right)=i$. The set of events is then $E=\{1,2, \cdots n\}$.

[^4]:    ${ }^{6}$ In order to not introduce unnecessary terminology, we abuse the term poset to mean the structure $(E, \ell, \leq, \vdash)$ where the set of events $E$ is equipped with two partial orders. We could instead define $\left(E, \ell,(<\cup \Vdash)^{\star}\right)$ but in this case we forget the distinction between $<$ and $\Vdash$.
